The answer is most positive and satisfactory. As will be seen from Table 2, in 110 cases treated by this method by twenty-two observers, ninety-nine patients were clinically cured, while eleven died. The standard of cure in these cases consisted of the return to normal formed stools, and a total absence of any dysenteric symptoms. Amebas had often entirely disappeared from the stools, but in other cases were still present. The significance of amebas persisting in the stools will be considered later. Meanwhile it is important to consider the eleven fatal cases.

One case reported by Rogers,[8] Case 3, was a case of gangrenous amebic dysentery in a confirmed opium-eater. Necropsy revealed most extensive ulceration affecting the whole length of the large intestine. The caput coli was gangrenous with little but the peritoneal coat remaining. A prolonged microscopic examination of scrapings of the ulcers in various parts of the bowel failed to reveal a single living ameba, and sections through the walls of the more recent ulcers showed not a single parasite.

Two other deaths are reported by Rogers[9] in cases ending fatally within three days after admission to hospital. To one who is familiar with amebic dysentery it is apparent that patients with this disease must be in a desperate condition indeed to die within three days of admission.

Baermann and Heinemann[10] treated twenty-two cases with seven deaths, which shows beyond a doubt that their cases were also in a very advanced stage. They themselves say, "with regard to these cases, a cure could not have been effected even if the amebas were killed and the ulcers healed. . . . Even these cases were interesting, for the necropsy showed almost without exception a complete recovery of the intestine. In no case could amebas be demonstrated in the mucous membrane either in superficial ulcers or in the undermined ulcers."

Lyons[11] reported one death, but says, "In fairness, however, this case should be omitted in judging the treatment, as the patient was beyond redemption." Cases

such as these eleven in which the patients were moribund should be excluded from consideration in passing on the value of a given treatment. It can be said that any amebic dysentery patient who is not moribund can be "cured" by emetin.

The rapidity of the improvement is also noteworthy. It has been customary to treat amebic dysentery for weeks or months often with little change in the symptoms. In these reported cases recovery has for the most part been so rapid as to be little short of marvelous. The effects of the treatment have been marked from the first injection; blood and mucus disappear from the stool, pain is entirely relieved, the number of stools is greatly reduced, and the patient gains rapidly in weight. In many of these reported cases the patients have obtained complete relief from their dysenteric symptoms within a week, after the use of very small amounts (from 2 to 3 grains) of emetin. In other cases, the disease has proved more resistant, and has required a longer course of treatment or the use of larger amounts of emetin to effect a "cure."

2. Is the emetin treatment effective in hepatitis? In sixteen cases reported by nine observers, sixteen patients, or 100 per cent., were "cured."

The use of the word "cured" in these cases is less objectionable than is usually the case, for not only have the patients obtained complete relief from the symptoms of the abscess, but the discharge has ceased, the wounds have healed, and in one or two cases[14] a subsequent Roentgen examination has indicated that the abscess cavity had entirely disappeared. Moreover, these cases up to date have shown none of that tendency to recurrence which is so frequent after surgical treatment and evacuation. Several of these cases were treated before suppuration occurred[7, 8] several after the formation of pus and without evacuation,[36] and several after evacuation of pus by rupture into the lung or the intestine.[15, 22] Several of these cases had been treated surgically and by the use of other drugs, such as quinin irrigations into the abscess cavity, without effect, and were considered as rather hopeless cases before emetin was tried.[28]

The uniform success reported in these cases is quite remarkable, since the mortality following liver amebic abscess has, in the past, been high, having been estimated at from 80 to 30 per cent., depending on the method of treatment. Müller[37] has recently reported twenty-four cases treated surgically, in which six patients (25 per cent.) died. This may be taken as representing the average result of good surgical treatment, and it is clear that the use of emetin in this condition is a therapeutic triumph.

3. Are these cases permanently cured? Amebic dysentery is notorious for its tendency to relapse. Patients recover only to develop a fresh exacerbation or perhaps a liver abscess after weeks or months of apparent freedom from the disease. Moreover, the patients that have been treated by emetin have in many cases continued to harbor amebas in the feces. Baermann and Heinemann used enormous doses of emetin without succeeding in finally eradicating the amebas from the feces although the patients were quite well. I have, myself, observed the same result in several cases in which the success of the emetin treatment was unquestionable. This result might, as a matter of fact, be expected, for no matter how poisonous the emetin in the circulation may be to the amebas in the tissues, the amebas in the lumen of the intestine, being to all intents and purposes outside of the

body, would not be subjected to its action. Now if amebas are still present in the patient's intestinal canal, what is to prevent a reinfection, even if every ameba in the tissues is killed? To this question no satisfactory answer can be given at present, but there are several points that may be noted. In the first place the observers who have so far reported these cases have not stated that *Entamoeba histolytica* was found in the stools after the emetin treatment. The fact that patients may harbor a double infection of *Entamoeba histolytica* and *Entamoeba coli* should not be forgotten. *Entamoeba coli* is a harmless commensal. We should not expect to remove it by the emetin treatment, nor is its continued presence of any significance. As I have satisfied myself in at least three cases, however, *Entamoeba histolytica* has remained, chiefly in the encysted form, in the feces, after treatment by emetin had dissipated all dysenteric symptoms, and after rectal examination had demonstrated that the ulcers previously present in the rectum were healed. Further, Walker's results[38] indicate that in such cured cases of amebic dysentery the patients continue to harbor *Entamoeba histolytica* for years and in fact become carriers of this infection. Thus Walker says, "None of the twenty experimentally infected or of the nine naturally infected men has ceased to be a 'carrier' of the *Entamoeba histolytica*, although some of them have been under observation for over two years."

The actual final results of the emetin treatment may prove to be much more satisfactory than these theoretical considerations would lead us to expect. For while these patients of Walker's continued to harbor *Entamoeba histolytica* for these long periods, he says specifically in the protocols of his experiments that these men developed no symptoms of dysentery after the primary attack had been cured by the administration of ipecac. In other words, it has been demonstrated that a man may continue to pass *Entamoeba histolytica* in his stools as long as two years and four months without ever developing any symptoms of dysentery. It would appear from this observation that, contrary to general belief, a man who has entirely recovered from amebic dysentery may be protected, in some way, against reinfection. The relapses that have been so frequent in this disease in the past may have been due to the fact that all the amebas in the tissues were killed in but few cases, and that the few remaining amebas subsequently caused the relapse. The final proof as to whether or not patients treated by emetin will remain "cured" can be determied only by observing these cases for a number of years. None of the cases so far reported fulfil this requirement. Through the courtesy of Lieut. Edgar F. Haines of the Medical Reserve Corps, however, I am enabled to report two cases in which the patients have remained well for periods of five and nine months. Lieutenant Haines treated these cases, and very kindly sent me the following notes:

Case 1.—Miss M., aged 34, school teacher, who had been in the tropics five years, in 1909 had had amebic dysentery and was treated at that time by quinin irrigations, since 1909 has had three or four attacks, each lasting from four to six days. In the latter part of February, 1913, she had another attack of diarrhea, which had lasted nearly two weeks when I was called to see her. Again she asserted that this was due to eating a certain fruit, which, she said, always brought on her trouble. Examination of the stools showed the presence of *Entamoeba histolytica* in large numbers. Emetin treatment was begun at once, ½-grain doses being used, one dose night and morning. Five grains were used in this case all told. All dysenteric symptoms cleared up immediately. Patient gained weight and was looking much better on my departure from the Philippine islands, April 19, 1913. Word received from this patient in August stated that she had had no recurrences and was in excellent health. Patient was up and about during treatment.

Case 2.—Mrs. H., aged 26, who had been in the tropics two and one-half years, and had been absolutely well during this time, in September, 1912, was taken with abdominal pains and frequent stools containing blood and mucus. She lost 10 pounds and became very anemic. On account of station, no microscopic examination of feces was made at this time. Ipecac was given with moderately good results. Pain ceased and stools became practically normal. In October, 1913, the patient had another attack similar to the one stated above; examination of the stools at Tien Tsin, China, failed to show the presence of amebas. It was advised that bismuth subnitrate be used; poor results were obtained from this treatment. For two or three days there would be an apparent improvement, then a relapse to former condition. This kept up until January, 1913, with periods of remission. By the latter part of January the patient had lost nearly 20 pounds, looked very anemic, was exceedingly weak, and was having three or four bloody stools a day. Examination of the stools made by Lieut. T. D. Woodson at the Division Hospital, Manila, P. I., and confirmed by myself, showed the presence of *Entamoeba histolytica* in large numbers. The patient was admitted to the Division Hospital, Manila, about Feb. 1, 1913. She could not retain ipecac. Bismuth subnitrate was used with no results. Emetin hydrochlorid (Merck) was begun about February 10, used hypodermically in ¼-grain doses, two doses a day, night and morning, until 3 grains had been taken. At the end of this time an opposite condition existed from a dysenteric one. The patient was up and about the third day after emetin treatment was stopped, and left the hospital on the fifth day. There was a slight recurrence one week after leaving hospital. Two ½-grain doses of emetin were given. All symptoms cleared up immediately. There has been no relapse since, up to the end of October (date of report). Weight is normal, no anemia and no pain are present, the stools are normal, and the patient feels fine. A total of 4 grains was used.

It may therefore be said that there is at least a possibility that some of the "cures" reported as a result of the emetin treatment of amebic dysentery may be permanent.

4. Have there been any ill effects following the emetin treatment?

In most of the reported cases the drug has been given hypodermically. Rogers[8] began by giving ⅓-grain doses, but rapidly increased them to ½ or ⅔ grain. These doses produced no ill effects. A number of observers have given as high as 1 grain at a single injection, with no bad systemic results, and Allan[23] on one occasion administered 4 grains of emetin hydrochlorid at a single dose. This caused nausea for several hours with vomiting once.

Baermann and Heinemann[10] say: "When the subcutaneous dose was increased from 120 to 150 mg. (from 2 to 2½ grains) in daily repeated injections, indisposition, weariness and loss of appetite were experienced. These phenomena disappear in from twenty-four to forty-eight hours after the use of emetin." Almost all of the observers who have used the larger doses have reported that they were painful. Intramuscular injections have been more painful than subcutaneous.

Intravenous injections have also been used. Rogers[39] reported the use of 1 grain intravenously with no bad results. Baermann and Heinemann say:

---

[38] Walker, E. L.: Experimental Entamoebic Dysentery, Philippine Jour. Sc., 1913, viii, Sec. B., 253.

[39] Rogers: The Rapid and Radical Cure of Amoebic Dysentery and Hepatitis by the Hypodermic Injection of Soluble Salts of Emetine, Therap. Gaz., 1912, Series 3, xxviii, 837.

> Intravenous injection of from 60 to 200 mg. caused no serious disturbance but slight dizziness, disturbance of vision and slight vomiting. When from 300 to 400 mg. were injected, we observed very serious symptoms, which began in from two to five minutes after the injection and consisted of general vascular paralysis, severe dyspnea, loss of consciousness with vomiting and passage of thin stools and great slowing of the pulse. We estimated the maximal intravenous dose as 250 mg. per 60 kg. of body-weight.

Since emetin, by many observers, has been regarded as a more or less harmless drug, and since I am of the opinion that the doses used by some and particularly by Baermann and Heinemann are too large, I wish to point out the possible danger in not using due caution in the use of this very potent remedy.

Sollmann,[40] with regard to ipecacuanha, says:

> Central symptoms make their appearance after large doses. Paralytic symptoms set in, among the earliest in mammals being vasomotor paralysis with fall of blood-pressure. This is further aided by weakening of the heart-muscle due to its direct muscle action. . . . Some persons are so sensitive to the local action of ipecac that the opening of a jar at a distance of several feet will produce violent sneezing and discomfort. . . . Cephaelin is far more emetic, *but emetin is much more depressing.*

Capt. Henry J. Nichols of the Medical Corps and I have found that 2.5 mg. per kilogram of emetin hydrochlorid intravenously is the minimum fatal dose for rabbits, while one rabbit died as the result of 20 mg. per kilogram administered subcutaneously. The rabbits to which the drug was given intravenously died in a few seconds, apparently as the result of centric paralysis. The subcutaneous and intramuscular injection of large doses caused considerable local irritation and even necrosis, particularly of the muscular tissue. I have found that 10 mg. of emetin hydrochlorid per kilogram subcutaneously on two successive days is a uniformly fatal dose for white rats. It would appear from these observations that the doses proposed by Baermann and Heinemann are far too large, and that if the drug is administered in such doses, fatalities will soon occur which will unjustly discredit the use of emetin. Furthermore, these tremendous doses appear to be entirely uncalled for, since success is commonly obtained in the treatment of amebic dysentery and hepatic abscess with doses not exceeding 1 grain (64 mg.) hypodermically. As has already been pointed out, it cannot be expected that the amebas in the stools will disappear even as the result of such heroic doses, and this should no longer be attempted.

5. What is the best method of treating amebic dysentery and hepatitis by emetin?

Theoretically, the intravenous method offers certain advantages, such as the prompt introduction of the drug into the circulation, and the possibility of accurately standardizing the dose. An irritating drug like emetin is of necessity slowly absorbed when injected subcutaneously. On the other hand, hypodermic medication is easier both for patient and physician, and, what is more important, safer. After seeing rabbits die immediately after intravenous injections of comparatively small amounts (from 3 to 5 mg.) of emetin hydrochlorid, I should hesitate before administering even 1 grain intravenously in a human case. If given to one of the patients so susceptible to the effects of ipecac mentioned by Sollmann, such a treatment would not improbably be followed by death. Several successful cases are reported[12, 39] in which the emetin was given by mouth. I have treated one case by this method without obtaining the striking results that follow the hypodermic use of emetin. The hypodermic method is therefore recommended.

Emetin hydrobromid and hydrochlorid have both been used, but the burden of evidence appears to favor the hydrochlorid, which is more soluble. This salt is on the market in the form of powder and ampules. The former the physician can prescribe to be put up in capsules, pills or in solution with sterilized water when indicated.

The customary procedure has been to administer doses varying from ⅓ grain to 1 grain daily for about ten days. Inasmuch as the larger doses are distinctly irritating, it appears preferable to me to give ⅓ grain three times a day for about ten days. In this manner a large amount of the drug can be administered without serious inconvenience of any kind. Vomiting has never been reported from the use of emetin in this dosage, *and the patients feel no general disturbance. On the* contrary, they usually experience the first sensations of well being that have been enjoyed for months. After such a course if the patient is clinically cured, the treatment should be suspended, and the patient's stools watched for *Entamoeba histolytica.* Any recurrence of dysenteric symptoms should be the signal for the prompt initiation of a second course of treatment. If the patient's stools have not become normal under this treatment, larger doses may be employed. Emetin at present is quite expensive, costing about fifty cents a grain.

Cases of amebic liver-abscess should be treated with emetin in the same manner and about the same dosage. If results are to be satisfactory, the diagnosis must be certain, for while emetin appears to be a true specific, and directly toxic toward amebas, its use in abscesses of bacterial origin will be unavailing.

Moreover, in cases of abscess with large accumulations of pus, although the amebas will be killed by the emetin, it cannot be expected that this pus will be absorbed. It is believed, therefore, that in case an amebic abscess has not ruptured spontaneously into the lung or intestine, exploratory puncture should be practiced. If pus is found, and amebas are demonstrated, the opening should be enlarged sufficiently to permit the abscess to be evacuated, and emetin should at once be administered. Since experience has shown that the emetin produces a prompt cessation of discharge, and completes the cure in a few days, it is no longer necessary to perform operations such as the best surgical practice now requires in order to secure free drainage. All that is necessary is to secure an evacuation of the pus present and to secure drainage for a few days. Possibly the old method recommended by Manson,[41] which has now given way to more complete surgical operations, may be advantageously reintroduced.

6. The treatment of carriers.—As previously pointed out, a large percentage of the patients with amebic dysentery so treated become chronic carriers of encysted amebas. In addition to the fact that, so far as we know at present, they are subject to reinfection, it seems probable that these cases are a menace to the community. Walker says:

> In consequence of the extremely feeble resistance of the motile *Entamoeba histolytica* to external influences, it is not considered that cases of acute entamebic dysentery are an important source of infection. On the other hand, it is believed that chronic and latent cases of this disease are the

---

[40] Sollmann: Text-Book of Pharmacology, p. 309

[41] Manson: Tropical Diseases, Ed. 4, p. 516.

chief, if not the exclusive source of infection in endemic regions, first, because of their relative prevalence; secondly, because this condition persists indefinitely; thirdly because their infection is unsuspected, and fourthly, because these "carriers" are constantly passing in the stools, often in enormous numbers, the resistant encysted stage of *Entamoeba histolytica.*

It is apparent that it is desirable for both personal and public reasons to rid these carriers of their infection. The emetin treatment fails to do this. Chauffard[40] attempted to destroy these amebas by giving an irrigation consisting of 100 mg. of emetin hydrochlorid dissolved in a liter of water. The result was very bad, being followed in the next twenty-four hours by fourteen liquid stools containing mucus and blood. Chauffard apparently considered this as a recrudescence of the previously cured dysentery, but it seems much more probable that these dysenteric symptoms were due to the irritating effect of the emetin. Emetin, therefore, should not be used for this purpose. My own investigations have shown that both quinin and silver nitrate are powerful amebacidal agents. The reason that irrigations with these drugs have usually failed in the past to cure dysentery has been that they did not reach the amebas in the tissues. Since, in the cases under consideration, the amebas in the tissues have all been killed by emetin, it seems probable that these carriers may be rid of their infection by repeated high irrigations of quinin and silver nitrate prepared and given as described by authorities on the treatment of amebic dysentery. If, as Walker maintains, dysentery is propagated almost solely by these carriers, careful observation and treatment of each case in this manner will not only eliminate the chances of recurrence in that individual, but, in the course of a few years, will greatly reduce the general incidence of this disease or perhaps even eradicate it.

7. *The use of emetin in other diseases.*—The results of the use of emetin in amebic disease have been so marvelous that there has been a natural tendency to extend this treatment to other diseases. Milian[42] suggested that since salvarsan is a powerful specific against syphilis, and has also been found to cure amebic dysentery, perhaps the reverse might be true and emetin might be a valuable drug in syphilis. He reported several cases of syphilis treated by emetin with more or less equivocal results. Roux and Tribondeau[20] also treated a case of syphilis with negative results. Experiments performed in this laboratory by Captain Nichols and myself have shown that intravenous injections of large doses of emetin hydrochlorid have no effect on the spirochetes in the chancre of a rabbit experimentally infected with syphilis. Captain Nichols has found that similar injections have failed to protect rabbits from developing rabies. My original experiments showed that no effect could be expected from emetin in bacillary dysentery. On the other hand, these experiments indicated that emetin killed one of the free living paramecia *in vitro*, and there is a possibility that this drug might be useful in dysentery caused by *Balantidium coli;* but so far as I am aware this possibility has not been tested clinically. Experiments, which I have performed in this laboratory, indicate that emetin is very slightly toxic for certain trypanosomes, but that the course of the infection cannot be influenced in experimental animals by anything less than fatal doses. Its use in such infections is therefore not very promising. It appears, therefore, that emetin is highly specific for amebas and possibly some other protozoa, and has little or no action against bacteria or spirochetes.

CONCLUSIONS

1. Emetin is a true specific in amebic dysentery and hepatitis, and the results obtained by its use compare very favorably with the results obtained with salvarsan in syphilis.
2. The hypodermic use of the hydrochlorid salt is the preferred method of treatment.
3. A large percentage of the cases so treated continue to harbor *Entamoeba histolytica* (often in the encysted and most dangerous form) in the feces for some time.
4. While in view of this fact it is impossible to state at present that patients treated by emetin will remain permanently cured, yet the prospects of obtaining permanent cures by this method are encouraging.
5. The presence of a considerable number of these chronic ameba carriers constitutes a sanitary menace to the community.
6. It is possible that the amebas may be removed from these carriers by a course of irrigations of quinin or silver nitrate.
7. Experiments have failed to show that emetin possesses any marked therapeutic virtue in bacillary dysentery, syphilis, rabies or trypanosomiasis.

Addendum.—Since this article was written, James[43] has examined the *Amoeba histolytica* in the stools of cases of amebic dysentery before and after the use of emetin. The specimens were fixed and stained. Marked degeneration of the nucleus and cytoplasm of the amebas was demonstrated after the use of emetin. This constitutes additional evidence as to the specific action of emetin on *Entamoeba histolytica.*

Dopter[44] has reported five cases of amebic hepatic abscess and forty-six cases of amebic dysentery, all successful. He notes that:

1. Emetin is of no use against lesions caused by other parasites.
2. It does not prevent relapses. Of the 46 cases, 10 have already relapsed. Two cases in 30 days, 3 after 3 months, 5 after 4 to 6 months. These relapses yield easily to a second treatment of emetin.
3. Abscess of liver may also appear after an apparent cure by emetin without fresh intestinal symptoms.
4. Emetin, so specific for vegetative amebas, appears to be devoid of power against the cysts.

Major Hartsock, M. C.,[45] reports three further cases of amebic dysentery also successfully treated by emetin hydrochlorid.

Trypsin and Amylopsin in Malaria.—According to Major F. W. Lambelle, the experience in China and India is that quinin is not a specific for malaria in all its forms. In his statement in *Public Health Reports,* Jan. 3, 1914, Lambelle states that patients frequently return to the hospitals, deaf from cinchonism, still ill from the fever, and showing traces of parasites in the peripheral blood. Lambelle, therefore, has used trypsin and amylopsin in the treatment of these cases, according to the suggestion of Beard. The preparations of these drugs are sterilized, and injections are made into the muscles of the buttock. The injection is given slowly, and some swelling remains for from twelve to twenty-four hours. In the cerebral type of fever, the headache vanishes, the skin becomes moist and the temperature falls in a few hours. A single injection is said to clear the peripheral blood of parasites; three injections, at intervals of about four days, are in most cases necessary to effect a cure.

THE FUNCTIONAL METRORRHAGIAS

THEIR NATURE AND CONTROL[*]

ARNOLD STURMDORF, M.D.
Professor of Gynecology, New York Polyclinic Medical School; Associate Surgeon, Woman's Hospital
NEW YORK

In the entire range of our daily gynecologic experience there is probably not another manifestation with which we are more familiar and of which we understand less than a bleeding uterus. Time-honored dogma has so habituated us to accept every concomitant pathologic element as the immediate and direct cause of the bleeding, that we have become entirely oblivious to the existence and significance of certain intrinsic intermediary factors that essentially link cause to effect and reveal the "why and how" of the uterine hemorrhage in logical sequence.

When a bleeding uterus presents a small fibroid, we seek no further for an explanation, and yet no one has definitely explained why one uterus harboring a fibrous nodule bleeds excessively, while another bearing enormous masses of a similar nature does not bleed at all. Still less do we know why there is bleeding from those uteri that present no palpable evidence of any causative factor whatsoever, and lastly, we know nothing of why and how the uterus bleeds during normal menstruation.

This is a very extensive theme, and the obvious limitations of the moment prompt me to plunge at once to the practical core of our subject by assuming that we are summoned to control a case of excessive uterine hemorrhage.

Our examination of the patient may reveal what we interpret as a cause for the bleeding, either pelvic or systemic; on the other hand, the most painstaking investigation may fail to develop any such cause, and these are the cases specifically embodied in the title of this paper. In either event, whether the cause of the hemorrhage is apparent or not, we promptly inaugurate the same venerable therapeutic triad, ergot, packing, and lastly but inevitably, the curet. The bleeding may cease and again it may not, in which event we shall probably renew and repeat our efforts along the same lines, ringing the changes among the alluringly named uterine styptics, until the persistence and gravity of the hemorrhage leaves us no choice but hysterectomy. This, of course, conquers the hemorrhage and removes all the evidences of our therapeutic impotence with the bleeding organ; but our clinical conscience may be much disturbed when the pathologist quietly informs us that we have deprived our patient of a normal uterus.

Two questions will naturally present themselves:

1. Why did this uterus bleed so persistently?
2. Why have we failed to control the bleeding?

The current literature teems with explanations. Every anatomic element of the female generative organs has been charged and acquitted as the causative factor: the endometrium, the adnexa, the myometrium and the uterine blood-vessels. We have scraped these uteri for endometritis and found only the hitherto misinterpreted morphologic changes in the endometrium, normal to the different stages of the menstrual cycle. We have removed diseased adnexa — and sometimes normal ones — and the bleeding continued or recurred. We have had fibrotic and endarterial degenerations in the myometrium of these uteri demonstrated, only to find the same alterations in non-hemorrhagic senescent uteri, and thus, all along the line, one after another of the alleged etiologic factors failed to exhibit that uniform synchronism with the hemorrhage essential to establish a direct relationship of cause and effect, so that, in the present state of our knowledge and according to all tenets of clinical nomenclature, the title of functional metrorrhagia is justified.

These cases occur most frequently, but not exclusively, at the two extremes of menstrual life; and while their diagnosis obviously rests on the exclusion of every demonstrable exciting factor, such an exclusion is not always possible under ordinary conditions, for there exist fundal polypi or short pediculate submucous myomas in the cornual recesses of the uterine cavity, and more important, certain forms of adenocarcinoma limited to the upper endometrial zone, the recognition of which is made possible only by a vaginal section of the cervix or, in other words, by a vaginal explorative hysterotomy.

To establish the functional nature of the condition is to establish a favorable prognosis; for, notwithstanding the persistence and gravity of the hemorrhage, it is well to bear in mind that most of these patients will tend toward recovery after a more or less protracted period—provided that during this period, which may last several months, the bleeding can be held within safe limits. It is axiomatic that every clinical manifestation represents a normal function perverted or diverted, and every therapeutic effort must be based on the normal mechanism of that function. Coagulation is Nature's universal hemostatic, and every effort to control bleeding must be an effort to induce coagulation.

I have already indicated that these hemorrhages present a perverted menstruation, and any one who has ever attempted, experimentally or otherwise, to check a normal menstrual bleeding will fully realize the therapeutic difficulties that confront us in the control of these abnormal types. It is a significant fact that, while the incoagulability of normal menstrual blood has been noted since earliest times, the identical incoagulability characterizing the cases under discussion has escaped the attention of all observers; and yet this same incoagulability in perverted protracted form embodies the etiology and dominates the treatment of the hemorrhage. The hitherto accepted teachings, attributing the absence of clotting in menstrual blood to the presence of alkaline mucus secreted by the endocervical glands, is no longer tenable, for no such admixture inhibits coagulation in other mucus-secreting areas.

It would lead far beyond the practical object of this paper to enter into the complex and important elucidation of this hematologic problem, for the details of which I must refer those specially interested to my former publications on the subject.[1] It must suffice here to state that the endometrium, during menstruation and in the hemorrhagic cases, receives normally coagulable blood from the general circulation and sheds this blood in a non-coagulable state. This loss of coagulability is not due to the absence or deterioration of any element essential to coagulation, but to the presence of an inhibiting substance that is periodically secreted by the corporeal endometrium, from which it may be expressed. Such expressed endometrical juice is capable of inhibiting coagulation in any normal blood.

---

[*] Presented before the Medical Society of the County of New York, Dec. 22, 1913.

[1] Sturmdorf, Arnold: Metrorrhagia and Uterine Fibrosis, Am. Jour. Obst. and Dis. of Women, 1910, lxi, No. 6; Studies on a Local Hematologic Factor in the Causation of Uterine Hemorrhage, New York State Jour. Med., October, 1911.

The endometrium is activated to the secretion of this inhibiting substance by a hormone generated in the graafian follicles. To the present time we have not succeeded in isolating this substance, nor have we discovered its specific antagonist, but we have learned to circumvent it by effectual measures. These measures must be focused on two objective points: the regulation of the systemic blood-pressure and the inhibition of the endometrial hyperactivity.

Whenever and wherever a copious hemorrhage occurs, Nature promptly diminishes the force and volume of the general blood-current by relaxing the cardiovascular channels. Even the normally menstruating woman regularly presents a drop of from 10 to 15 points in blood-pressure at the terminal stage of her menstrual period. The metrorrhagic cases, on the other hand, especially the preclimacterics, present a persistent high pressure, ranging from 150 mm. of mercury upward.

The indication for vasodilators is obvious. Under the guidance of a reliable pressure apparatus, aconite, nitroglycerin and especially atropin should be administered until the vascular hypertension is reduced to normal. Opium is a sovereign adjuvant and is indispensable in the cases characterized by cerebral erethysm and general restlessness, which, in itself, is productive of circulatory pressure. I mention ergot in order to condemn its use in the most emphatic terms. It does not and cannot control these metrorrhagias: its specific influence on the musculature of the puerperal uterus is never realized in the non-gravid organ, while its recognized augmentation of the general vascular tension only tends to increase or prolong the bleeding. The same applies to the use of hydrastin and cotton-root bark, while stypticin (cotarnin hydrochlorid), styptol (cotarnin phthalate) and all the later synthetic oxytoxics are absolutely inert.

I cannot enter on the outlines of the local treatment without a word of warning against the prevalent indiscriminate use of the curet, which, except for diagnostic purposes, has no place in our therapeutic armamentarium for this form of hemorrhage. The curet should never be used without an obvious indication, and the existence of such an indication places the case outside of our present category, for, as already stated, these are purely functional cases, with no organic lesions and a normal endometrium, the laceration of which by the curet only augments the hemorrhage.

Two topical medicaments, the correct application of which fulfil the local indications, correcting the perverted function without destroying it — in other words, moderating the bleeding to the rhythm and proportions of normal menstruation without destroying the endometrium — will be found in pure acetone and 16 per cent. dilution of liquor formaldehydi. Either of these agents is cautiously but copiously introduced into the uterine cavity by means of an intra-uterine syringe. The syringe holds ½ to 1 ounce. The uterine end of the cannula is wrapped in a thin layer of sterile gauze and thus introduced into the uterine cavity to the fundus. A free return flow must be assured by the patency of the cervical canal, and the vagina protected from the irritating fluid by proper lubrication. The syringe is slowly emptied of its contents and carefully withdrawn in such a manner as to leave its saturated wrapping in contact with the endometrium for twenty-four hours. A daily repetition of this procedure is essential.

The hemorrhage does not cease at once, but is steadily reduced until a slight seepage, which may last several weeks, during which time treatment must be persisted in, inaugurates a normal intermenstrual period.

Should this method fail, a few applications of the D'Arsonval spark, in the manner recently adopted for the treatment of vesical papillomas, will yield the desired result.

Such, in bare outline, are the principles that govern the control of these hemorrhages. They involve innumerable details which are necessarily omitted here. We must always bear in mind that we are dealing not merely with a bleeding uterus, but with a bleeding woman. The management of these patients offers the most legitimate field for so-called medical gynecology, and their successful control will often tax the skill, the patience and the therapeutic resources of the most experienced.

It is five years since I began this study and four years since my first publication on the subject. Much has come to light during that period, yet more remains to be solved. Nevertheless, at this writing I venture to assert that no pathologist will ever again have occasion to report that I have deprived a woman of a normal uterus for the control of grave functional metrorrhagia.

NEOSALVARSAN FROM THE FRENCH POINT OF VIEW

B. BARKER BEESON, M.D.
Assistant in Cutaneous Pathology, Rush Medical College
CHICAGO

Since this drug is rapidly superseding salvarsan, it is essential for us to become fully conversant with it. For a number of valuable observations regarding neosalvarsan we are indebted to the French. It shall therefore be my aim to make a brief summary of these.

The usual initial dose is 0.45 gm., although some prefer to begin with 0.3 gm. Ehrlich and Hata have advised that the dose of salvarsan be fixed at 0.01 gm. per kilogram of body-weight. Since neosalvarsan contains approximately 21 per cent. of arsenic and salvarsan 31 per cent., the dose of the former can be set at 0.015 gm. per kilogram, as Leredde has suggested. Three or four injections constitute a series. It has been shown that at least four days are required for the elimination of an intravenous injection of neosalvarsan. Most French clinicians administer injections seven or eight days apart.

If the first dose is well borne and there are no untoward symptoms, such as gastro-intestinal disturbances or headache, one could increase the next dose by 0.15 gm. This can be continued so that by the fourth injection the patient will be receiving 0.9 gm. Ravaut says that this figure should on no account be exceeded, but others, as Darier,[1] sometimes give 1.05 gm. One can also find those who mention larger doses, among them Leredde,[2] who, in cases of general paralysis and tabes dorsalis, has given a series of three injections of 0.9 gm., 1.2 gm. and 1.5 gm., respectively.

The solvent in most general use is distilled water. It must be freshly prepared and an apparatus composed entirely of glass is advised in order to avoid an impure product. Levy-Bing[3] advises the use of freshly distilled water, to each liter of which 1 c.c. of a normal solution of sodium carbonate has been added. In an exhaustive article, Emery[4] says that the apparatus employed for distillation should be made of Jena glass. Crystal, he says, is rich in lead silicate, ordinary white glass contains silicate of sodium, while potassium silicate is to be found in Bohemian glass. Jena glass is recommended as being free from these impurities.

---

[1] Darier: Bull. Soc. franç. de dermat. et de syph., 1912, p. 383.

[2] Leredde: Bull. Soc. franç. de dermat. et de syph., 1912, p. 428.

[3] Levy-Bing: Bull. Soc. franç. de dermat. et syph., 1912, p. 465.

As regards its administration, shall it be given in concentrated solution? It has been my good fortune to see and follow a large number of cases thus treated in Ravaut's service at Hôpital St. Louis as well as with Levy-Bing at Maison St. Lazare, and from the results obtained I have no hesitation in recommending it. Ravaut,[5] who was the first to give it in this form, administers neosalvarsan up to 0.9 gm. doses in 10 c.c. of freshly distilled water and says that this amount of water may be further reduced.

His technic is as follows: The required amount of distilled water is poured into a small glass container and the neosalvarsan added. As soon as solution has occurred the liquid is drawn up into the glass syringe, which is equipped with a special aspirator-filter. The latter is detached. the needle put on and introduced into the selected vein, and, as soon as its entrance is announced by the outpouring of blood into the syringe, the dose is given. The whole operation is easily accomplished in about one minute. At St. Lazare the desired amount of neosalvarsan is dissolved in 25 c.c. of distilled water.

The intravenous route is preferred and in the great majority of cases is the one selected, but the intramuscular method is also followed by some. Balzer[6] of Hôpital St. Louis has used it extensively as follows: Neosalvarsan 0.3 gm., suspended in 1 c.c. of oil and the whole enclosed in a glass ampule, is the form in which the drug is furnished. The muscles of the lumbar region are best suited for injection by this method. The patient reclines face downward, a needle is inserted into the muscle on each side of and close to the spinal column, just above the iliac crest. The required dose is drawn up into the syringe, which is then attached to the needle, and the injection is made. One should not omit waiting at least one minute after the introduction of the needle before proceeding with the injection, for should bleeding occur the needle must be withdrawn and reinserted. This is done, of course, to obviate embolism, which would result should any of the oily mixture be injected directly into a blood-vessel. The gluteal region may be utilized and one-half the dose injected into each buttock in a similar manner. One such injection can be given every eight days, and six would constitute a series. Balzer has also employed, in a few cases, a mixture of neosalvarsan 0.3 gm., and gray oil 0.05 to 0.07 gm. in each dose. This was used after the manner in which the intramuscular injection already referred to was used. No bad results followed the employment of this mixture, nor was any decomposition of the neosalvarsan in the presence of the hydrargyrum noted.

SEQUELAE OF INTRAVENOUS INJECTION

The phenomena which follow an intravenous injection of neosalvarsan may be briefly summarized as follows:

1. *Elevation of Temperature.*—When present, it usually begins six or eight hours after the injection. It is more frequent after the first than those given subsequently. In a series of 191 injections Ravaut ascertained an elevation of temperature above 38 C. (100.4 F.) fifty-one times. The temperature usually drops to normal within twenty-four hours.

Certain syphilographers, among them Jeanselme, state that the fever which follows the initial injection of neosalvarsan is a specific one, due to the destruction of the spirochete, and further that it possesses the same significance as that which follows the injection of tuberculin in tuberculosis. This statement is strengthened by the fact that in a large number of skin diseases treated with intravenous injections of neosalvarsan, among them leprosy, sporotrichosis, mycosis fungoides, sarcoid and dermatitis herpetiformis, this rise in temperature was not detected.

Observations made by Brocq are of interest as showing that in different stages of syphilis the febrile reaction varies. Those treated with neosalvarsan during the period of the initial lesion showed a temperature of 37.5 C. (99.5 F.), 37.8 C. (100.04 F.) rarely 38 C. During the secondary stage slightly higher readings were recorded up to 38.5 C. (101.3 F.). The highest temperature reached was found in those suffering from the graver manifestations of syphilis. Among them an elevation to 40 C. (104 F.) was not uncommon.

2. *Headache.*—This is of frequent occurrence following the initial injection, in 45 per cent. of all cases. according to Milian. It usually appears a few hours after the injection, but its duration does not usually exceed twenty-four hours. Should the patient complain of headache following his first injection, one need not attach any particular significance to it. But if, on the other hand, it is noted after several, the physician should be on his guard and examine the nervous system of his patient at once. This can be done clinically or biologically. The latter method is more delicate and accurate. Spinal puncture having been performed, the fluid which has been withdrawn should be examined microscopically with regard to the presence of an increased number of lymphocytes and chemically for albumin, and it can be further tested by means of the Wassermann reaction. The degree of pressure under which the fluid issues should not be overlooked.

3. *Nausea and Vomiting.*—These, like fever and headache, appear most frequently after the first injection, but may come more quickly, sometimes almost immediately after the neosalvarsan has been given. In his series of injections which has been already mentioned, Ravaut noted nausea twenty-two times and vomiting ten times. He believes that these can in most cases be avoided by a preliminary course of mercurial injections.

4. *Diarrhea.*—A serous diarrhea has been observed, usually on the night following the injections. It is generally mild in character and only found after the initial treatment as a rule.

5. *Cutaneous Manifestations.*—Generalized scarlatiniform eruption, bullous eruptions, herpes zoster, urticaria, herpes simplex and morbilliform erythemata have been observed.

6. *Miscellaneous.*—Icterus with enlarged liver, neuritis plus the classical picture of arsenical paralysis, deafness and others too numerous to be considered, have been reported.

There is a noticeable tendency toward reducing the number of conditions in which the use of neosalvarsan is contra-indicated. The following are the chief contra-indications: In nephritis (some advise the use of neosalvarsan when the renal lesion is luetic), myocarditis, chronic alcoholism, acute inflammation of the lungs and upper air-passages and gastric or duodenal ulcer. As to tabes and general paralysis in advanced stages, it is the opinion that they should be treated with this agent even though one is forced to give a small dose. In the incipient stages of these two diseases large doses can be given.

---

[4] Emery: Bull. Soc. franç. de dermat. et de syph., 1912, p. 461.

[5] Ravaut: Ann. de dermat. et de syph., April, 1913, p. 206.

[6] Balzer: Presse méd., April 2, 1913; Bull. Soc. franç. de dermat. et de syph., 1913, p. 92.

With regard to the effect of neosalvarsan on the various lesions of lues most French syphiligraphers seem in accord with the conclusions of Brocq,[7] who, while believing it to be a most efficient preparation, does not hesitate to say that a prolonged and intensive mercurial treatment should follow each course of injections. He also believes that the combined action of mercury and arsenic is infinitely superior to the employment of either one alone. Neosalvarsan is admitted to be equally as efficient as salvarsan without several of its disadvantages.

SUMMARY

1. The initial dose of neosalvarsan in most cases should not exceed 0.45 gm.
2. At least seven days should elapse before a second injection is given.
3. If following several injections, signs of intolerance are noted, the dose should be kept at the same figure, and reduced if the symptoms do not disappear following further treatment.
4. Distilled water is the best solvent.
5. Administration in concentrated solution seems to be the superior method.
6. Distillation should be performed in an apparatus composed wholly of glass.
7. The intravenous method is the one of choice.
8. Continued headache should be regarded as indicating possible involvement of the nervous system.
9. Neosalvarsan has a most efficient ally in mercury.

802 West Madison Street.

EFFECT OF LACTIC ACID BACILLI ON DIPHTHERIA

S. T. NICHOLSON, Jr., M.D.
AND
JOHN F. HOGAN, M.D.
BALTIMORE

Owing to the small number of beds available for the treatment of diphtheria in the Baltimore Municipal Hospital for Infectious Diseases, and to the increasing demand for institutional treatment of this disease, every suggestion for ridding the nose and throat of the Klebs-Löffler bacilli has been carefully considered by us and in most instances put to test.

The outcome of those tests gave no better results in our hands than our former routine, but we did not use the *Staphylococcus aureus* spray, described by Schiøtz,[1] as an overrider on account of its virulency. We perhaps were influenced more by the unfavorable reports than the favorable. Davis,[2] among others reported a case of severe tonsillitis following the use of this spray.

The routine of this hospital for the treatment of diphtheritic noses and throats consists of thorough irrigations of both parts with warm normal salt solution (by gravity) on admission, and frequent subsequent gargling or spraying with liquor sodii boratis compositus and liquor iodi carbolatus, and occasional swabbing with a 5 per cent. silver nitrate solution.

In addition to this routine, the suggestion of Wood[3] for the use of the live lactic acid bacillus spray for diphtheria as an overrider was done and gives promise of being a valuable addition.

We have employed this method in nine cases with results that are more pleasing than those from any other method at our disposal. These cases were not selected, but taken as they were admitted as bacteriologic and clinical diphtheria with the exception of Case 3, which was a bacteriologic case only. Our former treatment for the typical carriers differs somewhat from the routine mentioned above in that in these cases the tonsils are distended with sterile normal salt solution or with antitoxin by the injection of either directly into the tonsillar tissue, the surface of the tonsils then being swabbed with liquor iodi carbolatus. In Case 3 the live lactic bacilli were sprayed instead of using the antiseptic swabs.

We obtained cultures of the live lactic acid bacilli (Bulgarian type) from the Mulford laboratories in 20 c.c. tubes.

A small atomizer was used to distribute the culture in the nose and throat. This method was used in four cases. Ordinary sour milk was used in five cases in the form of a gargle for the throat and spray for the nose. It might be mentioned that no antiseptic gargles or sprays were used in these nine cases and we have treated some others, in which both were used with practically the same results as below.

LACTIC ACID

Case 1.—Girl, aged 4. Onset Sept. 12, 1913, with a sore throat. Admitted to Sydenham Hospital, September 17. Received no treatment prior to admission. Examination of the throat revealed a thick grayish membrane on each tonsil. Culture positive to Klebs-Löffler bacilli. On admission 10,000 units antidiphtheritic serum given.

September 18: Throat sprayed with two tubes of pure culture of lactic acid bacillus.

September 19 and 20: Cultures taken on these days were positive. Throat sprayed as on the 18th.

September 21: Culture taken on this day was slightly positive (but two or three Klebs-Löffler bacilli could be seen).

September 22, 23 and 24: Cultures taken on these dates were negative.

Summary: A negative culture was obtained four days after treatment was started with pure cultures of lactic acid bacillus, and but five days had elapsed since the antidiphtheritic serum had been given.

Case 2.—Girl, aged 2½. Onset Sept. 15, 1913. Admitted to Sydenham Hospital, Sept. 17, 1913. Examination on admission showed that each tonsil contained a small patch of membrane. Culture positive in Klebs-Löffler bacilli. Five thousand units antidiphtheritic serum given.

September 23: Culture positive.

September 24: Culture still positive. Throat sprayed with pure culture of lactic acid bacilli (Bulgarian type) at 2 p. m.

September 25: Culture slightly positive. Throat sprayed as on the 24th, at 11 a. m.

September 26 and 27: Culture negative to B. diphtheriae.

---

[2] Davis, Clara M.: Tonsillitis Following the Use of the Staphylococcus Spray, The Journal A. M. A., Aug. 9, 1913, p. 393.

[3] Wood, Harold B.: Lactic Acid Bacillus Spray for Diphtheria, The Journal A. M. A., Aug. 9, 1913, p. 392.

Case 3.—Girl, aged 14. Admitted to the Sydenham Hospital Oct. 6, 1913. Culture, examined by the city health department on account of diphtheria being in the family, was found positive Oct. 5, 1913. Examination reveals the absence of membrane on the tonsils, but they are enlarged and injected. Five thousand units antidiphtheritic serum given.

October 7: Throat sprayed with lactic acid bacilli (pure culture of the Bulgarian type).

October 8: Culture positive to *B. diphtheriae.*

October 9 and 10: Cultures negative.

Case 4.—Girl, aged 8. Admitted to Sydenham Hospital on October 15, twenty-four hours after the onset. Each tonsil contained a small patch of whitish membrane. Culture taken on this date was positive to Klebs-Löffler bacilli. Five thousand units antidiphtheritic serum given.

October 16: Culture taken at 11:30 a. m. positive. Throat sprayed with pure culture lactic acid bacilli (Bulgarian type) at 12 m.

October 17: Culture taken at 4 p. m. negative. Throat sprayed, as on previous day, at 4:30.

October 18, 19 and 20: Cultures taken at 11 a. m. each day negative.

SOUR MILK

Case 5.—Woman, aged 25. Admitted to Sydenham Hospital Nov. 9, 1913, the date of the onset. Examination reveals a whitish, ragged membrane extending over the surface of both tonsils and posterior pharynx. Ten thousand units antitoxin given. Culture positive to *B. diphtheriae.*

November 11: Membrane beginning to disintegrate but tonsils still very edematous. Five thousand units antidiphtheritic serum given.

November 17: Culture taken at 2 p. m. positive. Sour milk used as gargle from this time (2 p. m.) until midnight, every three hours.

November 18, 19 and 20: Cultures each day negative. Sour milk used as gargle every two hours from noon until midnight on the 18th and 19th.

Case 6.—Girl, aged 18. Onset November 9, with sore throat and malaise. Examination shows on both tonsils a whitish membrane on a red edematous base. The posterior pharynx is greatly injected and swollen.

November 11: Admitted to Sydenham Hospital and 5,000 units of antidiphtheritic serum given. Five thousand units of antitoxin given the day previous to admission (Nov. 10, 1913).

November 15: Membrane has disappeared.

November 17: Culture taken at 2 p. m. positive to *B. diphtheriae.* Sour milk used as gargle from 2 p. m. until midnight, every two hours.

November 19 and 20: Cultures taken at 11 a. m. each day negative to *B. diphtheriae.* Sour milk used as gargle every two hours from noon until midnight.

November 22: Edema has completely disappeared and with the exception of a slight enlargement of the tonsils, throat has a normal appearance.

Case 7.—Girl, aged 14. Admitted to Sydenham Hospital Nov. 10, 1913. Onset November 2, with cold in the head. Examination shows breathing labored, lips and mucous membranes are cyanotic, continuous bleeding from nose and dried blood on face around nose. There is a retraction of interspaces and patient cannot speak above a whisper. There was a small patch of grayish membrane on each tonsil.

November 10: Fifteen thousand units antidiphtheritic serum given. Culture positive to *B. diphtheriae.*

November 15: Culture positive.

November 17: Culture positive. Sour milk used as gargle every three hours from noon until midnight.

November 18 and 19: Culture taken at 11 a. m. negative. Sour milk used as gargle every two hours from noon until midnight.

November 21: Culture negative.

Case 8.—Girl, aged 8. Onset Nov. 18, 1913, with sore throat. Culture taken November 19 and examined by health department positive to *B. diphtheriae.*

November 20: Patient admitted to Sydenham Hospital at 1 p. m. Culture taken on admission positive. Throat gargled every two hours with sour milk from taking of culture until midnight. Examination showed both tonsils completely covered with a thick grayish membrane.

November 21: Culture positive. Sour milk used as gargle from noon until midnight. Membrane not so thick and beginning to disintegrate.

November 22: Culture taken at 11 a. m. positive. Membrane almost gone, but a small patch present on left tonsil.

November 23: Membrane entirely gone. Culture taken at 11 a. m. positive. Sour milk used as gargle from noon until midnight every two hours.

November 24, 25 and 26: Cultures negative. Sour milk used as gargle from noon until midnight.

Case 9.—Girl, aged 6. Onset Nov. 25, 1913, with sore throat. Admitted to Sydenham Hospital Nov. 26, 1913. Examination showed tonsils enlarged, hyperemic and edematous; a patch of thick grayish membrane on left tonsil.

November 26: Five thousand units of antidiphtheritic serum given at 12:15 p. m. Culture taken at this time positive. Sour milk used as a gargle from noon until midnight.

November 27, 28 and 29: Cultures positive. Sour milk gargle used from noon until midnight.

November 30 and December 1: Cultures negative.

SUMMARY

The results of the use of the lactic acid bacillus and sour milk in these few cases are encouraging enough for us to make a further study in this direction.

With the use of it and the intravenous method of administering antitoxin which will be published in a later paper, the patients are kept in the hospital a shorter period of time than formerly.

Before a definite conclusion can be reached in regard to the effect that these organisms have on the Klebs-Löffler bacilli and the cause of the antagonism between the organisms, however, a large series of cases must be studied—a series that extends over a long period of time in which comparisons can be made with the former methods of treatment.

Our part in this is simply a partial appliance of a method recommended by another.

Sydenham Hospital.

THE PRECIPITATION OF COLLOIDAL GOLD

A SPECIFIC REACTION IN THE SPINAL FLUID

D. M. KAPLAN, M.D.
Director of the Laboratory, Neurological Institute
AND
J. E. McCLELLAND, A.B., M.D.
Resident Physician, First Division Neurological Institute
NEW YORK

The discovery of the principle of complement deviation, and its application to syphilis by Wassermann, introduced a new era in medicine. Deviation for diseases other than syphilis have been elaborated with varying success, and attempts have been made by some to simplify and by others to render more delicate the original method suggested by the discoverer of the reaction. The significance of the entire test was for a time under discussion, but thanks to laboratory workers the importance of the Wassermann reaction has received a definite status and has been so well studied that, in conjunction with the analysis of the cerebrospinal fluid, it occupies a position second to none in the neurologic laboratory to-day.

A series of tests have been introduced for rendering assistance especially in neurologic cases, and it seems that the endeavors along this line are by no means exhausted. Most of these experiments have utilized the cerebrospinal fluid, and it is concerning one of the more recent of these tests that we wish to draw attention and report our findings. This test is called the goldsol or gold chlorid precipitation test, and was first worked out by Carl Lange.

Lange[1] says that in order to ascertain the exact nature of the globulin in the cerebrospinal fluid he has made use of the most delicate known method in the field of protein analysis, namely, the determination of the gold number (*Goldzahl*) according to the method worked out by Zsigmondy. In Lange's article it is apparent that the sole purpose of the investigation was to determine the chemical nature of the substance in the cerebrospinal fluid commonly spoken of as globulin, and obtained *in vitro* by Nonne's half saturation with ammonium sulphate solution and known as "Phase 1" reaction. This substance has been subjected to the large number of reactions usually employed in the analysis of proteins, as well as to the determination of the gold number. The results obtained with the latter method, with fluids from patients with syphilitic diseases of the nervous system, suggested to Lange the possibility of using it as a specific test for syphilis of the nervous system. At any rate the conclusion at the end of his paper neglects to tell us the nature of the protein substance, the point which he set out to establish.

The technic, according to Lange, depends chiefly on the proper preparation of the reagent. He describes a color-scale to correspond with varying degrees of gold precipitation; this scale reads from a clear watery white, which is obtained with complete precipitation, through the partial precipitations giving, respectively, white-blue, light blue, dark blue, violet, blue-red and red-blue, to the original red of the indicator. Besides these color changes, Lange considers as important the dilution in which the precipitation takes place. In his experiments the dilutions varied from 1 : 10 to 1 : 40,000.

In expressing his results graphically, Lange places the abscissa line at the top; in our work we have followed the usual custom and placed the abscissa at the bottom.

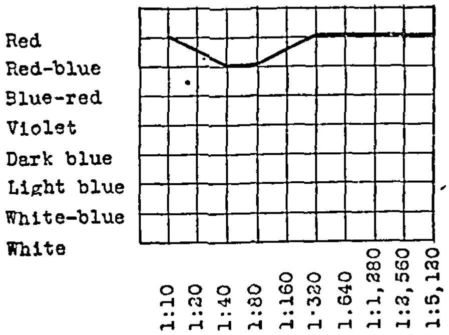

Chart 1.—Curve obtained in a case of secondary syphilis with headaches (reproduced from Lange).

For the sake of comparison we reproduce one of Lange's curves (Chart 1), which was obtained in a case of secondary syphilis with headaches. In Lange's article this is the only curve given with explanatory data; the other curves are without numbers and without color-scale, thus rendering difficult the correct interpretation. The article concludes with several tables giving the result of the gold precipitation expressed in a number of pluses, the complete precipitation being recorded as five pluses.

The cerebrospinal fluids from twenty non-syphilitic patients were analyzed and gave negative results. The fluids from cases of paresis were recorded with a number of pluses varying from three to five. Fluids from cases of secondary syphilis with headaches also showed five pluses.

The entire work of Lange included less than a hundred cases. A few excellent color-plates accompany his communication. His conclusion is that the reaction is significant of syphilis of the nervous system, and he suggests that patients with syphilis should have this test performed in addition to those usually employed. He says that it is particularly to be recommended in cases in which only a small amount of spinal fluid is available, and that it is also very useful in those cases in which syphilis is suspected and yet there are no clinical evidences of the disease.

A few American workers have repeated Lange's work and have verified his conclusions. Grulee and Moody also assert that they have found the test of value in diagnosticating cases of congenital lues without neurologic manifestations.

Our results do not entirely coincide with those of Lange and his followers in America. In general, we have found that this test is not a specific one for syphilitic disease of the nervous system, but when all the curves are compared, it is found that a characteristic reaction obtains in practically all cases of general paresis and in most of the cases of taboparesis. The fact that in taboparesis the curve is almost identical with that of general paresis is very interesting from both the laboratory and clinical points of view. The persistence of the characteristic curve in well-treated cases of general paresis reminds one of the "Wassermann-fast" condition in the serum which is present in these cases, and may prove to be a valuable laboratory help in differentiating general paresis from cerebrospinal lues and other pathologic states simulating paresis.

Before presenting our results it is advisable to describe briefly the technic, emphasizing certain salient points for properly carrying out this test.

TECHNIC EMPLOYED

The following stock solutions are used:

10 per cent. sodium chlorid solution, made from Merck's C. P. crystals.
1 per cent. gold chlorid solution, made from Merck's C. P. crystals.
2 per cent. potassium carbonate solution.
0.75 per cent. formaldehyd solution.

From the 10 per cent. sodium chlorid solution a 0.4 per cent. solution is to be freshly prepared for each day's tests.

PREPARATION OF THE COLLOIDAL GOLD

The proper preparation of this reagent is the most important as well as the most difficult part of the technic.

We have been in the habit of making up 500 c.c. at a time as follows: In a liter Florence flask of Jena glass (Lange recommends a beaker) which has been thoroughly cleansed with strong hydrochloric acid, water, distilled water and double-distilled water, are poured 500 c.c. of fresh double-distilled water. It is important to note that no rubber stopper or rubber connection should come in contact with the steam or with the distilled water.

Five c.c. of the potassium carbonate solution are added and the flask placed over the flame for one minute and 5 c.c. of 1 per cent. gold chlorid solution added. The heating is continued until the first bubbles appear; the flame is turned off and 5 c.c. of the formaldehyd solution allowed to run in gradually. During the addition of the formaldehyd the flask must be constantly shaken until the solution changes to a deep port-wine color. This is the colloidal gold solution, and it should be absolutely transparent, and when viewed by reflected light should permit the reading of ordinary newspaper print. It should not show a brown shimmer or a bluish color, nor should there be a bluish precipitate or any discoloration on the sides of the flask. It is safer to discard solutions that do not answer these requirements, as errors and false curves are liable to result from their use.

---

[1] Lange, Carl: Ztschr. f. Chemotherap., 1912, i, Part 1.

As a standard of color comparison we make use of 10 c.c. of a tenth-normal sodium hydroxid solution plus 1 c.c. of a Congo-red solution and 0.5 c.c. of an alcoholic alizarin solution. This gives a color matching exactly the correct color of the properly prepared colloidal gold. The comparison is to be made by transmitted light.

PERFORMANCE OF THE TEST

Into the first of a series of ten test-tubes are placed 1.8 c.c. of the 0.4 per cent. freshly prepared sodium chlorid solution, and into each of the others 1 c.c. To the first test-tube is now added 0.2 c.c. of the spinal fluid to be tested, measured accurately. This is thoroughly mixed by shaking and drawing up a 1-c.c. pipet several times. This gives a dilution of 1:10. One c.c. is now transferred from the first to the second tube and thoroughly mixed as directed before. This gives a dilution of the spinal fluid of 1:20 in the second tube; 1 c.c. of the solution in the second tube is transferred to the third test-tube, in which the dilution becomes 1:40 and so on through the series, giving a final dilution of one in 5,120 in the tenth test-tube.

Five c.c. of the gold chlorid solution are now added to each of the tubes and thoroughly shaken to insure perfect mixing of the fluid and reagent. If the reaction is going to be positive, a change in color of the indicator from red to a bluish hue takes place in a few minutes, but the final reading should be made only after from twelve to twenty-four hours. It has been our practice to allow all tests to stand over night. The total precipitation of the gold causes a complete disappearance of the red color of the indicator, giving a watery clear solution. Following the custom of other writers, we represent this complete precipitation as No. 5 on the ordinates (all results are best expressed in graphic curves on cross-section paper), a light blue almost clear fluid is designated as No. 4, and the next change is a deeper blue, which is No. 3; a reddish blue is No. 2, a slightly changed red is No. 1, and no change whatsoever is zero. Nicer color distinctions can be interpolated, but the foregoing scale is sufficient as a satisfactory working basis.

PRECAUTIONS

1. The spinal fluid should be clear, fresh and free from red blood-cells or other contaminations.
2. The lumbar-puncture needle should contain no rust, and should be cleansed with alcohol and ether before being sterilized.
3. There must be thorough and proper mixing both before and after the addition of the indicator to insure accurate dilutions.
4. All test-tubes should be thoroughly cleansed and sterilized. Pseudoreactions will result through omission of this detail.
5. All pipets should be treated in a similar manner.
6. For each fluid use a fresh pipet.

MATERIAL

For the sake of economizing space we print one curve (Chart 2) in full and give a few figures from which remaining curves can be reconstructed; for example, the color-changes given by Mr. Kin., expressed numerically for the various dilutions, were 5 5 5 5 5 4 3 2 0 0, the curve for which is shown in Figure 2.

In reproducing the curves the majority will have no numbers to indicate the dilutions; it will be taken for granted that the first number represents the first tube or the 1 : 10 dilution, and the tenth number represents the change in the tenth tube, or 1 : 5,120. With this explanation it will be very easy to reconstruct the curve.

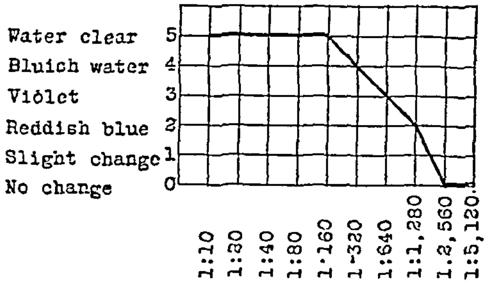

Chart 2.—Construction of curve for color-changes expressed by the numerals 5 5 5 5 5 4 3 2 0 0.

The fluids analyzed by us were chiefly from patients with organic disease of the nervous system; a few were from functional cases and an even smaller number were from cases commonly classified as medical cases. We have analyzed to date approximately 250 spinal fluids and have subdivided our results into two classes, A, nonlues, and B, syphilitic disease of the nervous system. Class B is subdivided into (1) cerebrospinal syphilis, (2) tabes, (3) taboparesis, and (4) general paresis.

TABLE 1.—CLASS A, NON-LUES

		Serology*

Summary: Characteristic G. P. curve obtained in 5 cases; 10 analyses; negative, 2; positive, 8.

(4) General paresis

		Serology					
Name	Treatment	S.W.	F.W.	Gl.	Pl.	Remarks	Gold Curve
Roo.	....	+	+	+	16	....	4 4 4 3 3 3 2 0 0 0
Kat.	....	+	+	+	46	....	5 5 5 4 2 2 1 1 0 0
Has.	....	+	+	+	70	....	5 5 1 0 0 0 0 0 0 0

Summary: Characteristic curve in 19 cases; 21 analyses; negative, 0; positive, 21.

When more than one test has been performed on the same patient, the subsequent tests were made only after intervals during which specific treatment had been given. These details are noted in the tables. The tables also contain the usual laboratory data.

All cases in which the diagnosis could not be definitely established were omitted from the tables.

In Table 1, a case diagnosticated as spinal cord tumor, did not give the excess of globulin which is usually found in these cases; but the diagnosis was confirmed at the operation. Case 16 gave a curve similar to those obtained in typical cases of general paralysis; but the clinical diagnosis of multiple sclerosis was clearly the correct one.

CONCLUSIONS

1. We have been unable to corroborate fully the results obtained by the other workers who have asserted that this reaction can be obtained in all cases of syphilitic disease of the nervous system.

2. The most marked reactions and typical curves are obtained only in cases of general paralysis and taboparesis.

3. A positive reaction occurs in most cases of cerebrospinal syphilis, but the curve is not characteristic.

4. In the majority of the cases of tabes either no reaction occurs or only a weak reaction in the 1 : 10, 1 : 20 or 1 : 40 tube.

AN IMPROVED TECHNIC FOR THE DOREMUS-HINDS UREOMETER

CHARLES J. ROBINSON, B.S., Ph.D.
AND
J. H. MUELLER, B.S.
LOUISVILLE, KY.

It is a matter of common knowledge that the estimation of urea by the Doremus-Hinds ureometer involves some error. Nevertheless, this method continues to be almost universally employed by clinicians in routine analysis, doubtless because the more accurate methods[1] seem rather formidable for the average laboratory facilities and often the limited time of the clinical analyst. Hence a simple way of minimizing the error in this very convenient method may be of some value.

According to our observations, the greater part of the error commonly encountered in this determination is due to a fault in the technic of the method. This fault is traceable to the text-books on urinalysis, chemical diagnosis, etc. The directions usually given for carrying out the test specify that after the urine has been introduced into the hypobromite solution, the instrument should be allowed to stand "for a short time," or "from ten to twenty minutes" before the reading is taken. Doubtless every one who has used the method has noticed that minute bubbles of gas continue to rise for a much longer time than that specified. Table 1 shows that this evolution of minute bubbles, extending over a long time, should not be neglected.

It is at once apparent that the readings taken at twenty minutes, according to the text-book directions, are so far below the true figure for urea as to be absolutely worthless. It is equally apparent that there is no regularity in the relation of this first reading to the true value, the first reading sometimes being less than 45 per cent. of the correct figure, sometimes being as much as 95 per cent. of the correct. Such a high reading, however, occurred very seldom. The temperature had little or no part in this, for the laboratory temperature never varied more than 4 or 5 degrees C. while the experiments were being carried out, and the method worked just the same in a warm room as in a cold one.

Consideration of the results of a large number of analyses of pure urea solution and urines showed no definite relation between the time of reading and the relative completeness of the reaction, when the ureometer was allowed to stand quietly. In the samples of urine, the urea was determined by the phosphoric acid method of Folin and Pettibone.[2] Assuming that the latter method gives correct results, we found that the correct figure was reached with the ureometer in periods of time varying from 5 to 24 hours, the periods in one set of readings chosen at random being 16, 5, 19, 19, 24 and 22 hours.

TABLE 1.—READINGS TAKEN AT INTERVALS WITH SIX DIFFERENT UREOMETERS (DOREMUS-HINDS)*

	20 min.	30 min.	1 hr	2 hr.	3 hr.	15 hr.	24 hr.	Actual Amount, mg.

4.	11.0	11.5	12.6	13.2	14.7	14.8	15.3	15
5.	7.1	7.7	8.5	9.3	10.3	13.2	14.0	15
6.	10.6	11.0	12.2	13.0	13.2	14.0	14.3	15
Average..	8.7	9.3	10.8	11.4	12.2	13.8	14.3	15

	20 min.	30 min.	1 hr.	2 hr.	3 hr.	5 hr.	24 hr.	Actual Amount, mg.
1.	13.3	13.5	14.0	14.1	14.3	14.3	14.4	15
2.	13.0	13 8	15.5	15.7	15.8	15.8	15.8	15
3.	13.0	13.5	14.5	14.7	15.0	15.0	15.1	15
4.	13.8	14.4	15.1	15.4	15.5	15.5	15.5	15
5.	13.0	13.4	14.0	14.1	14.1	14.1	14.6	15
6.	14.5	14.8	14.9	15.3	15.4	15.4	15.5	15
Average..	13.4	13.9	14.7	14.9	15.0	15.0	15.1	15

These two sets of readings are selected at random from a large number of similar sets.

* Pure urea solution was used containing 15 mg. per cubic centimeter. Figures express milligrams per cubic centimeter.

Finally it was seen that the explanation of these inconsistently variable results must lie in the amount of diffusion which takes place between the urea solution or urine, and the hypobromite solution at the moment of introduction of the former into the latter, and also the rate of intermingling thereafter. The density of the former being much lower than that of the hypobromite, it rises to the top of the column of liquid even when introduced slowly, before all of the urea has come in contact with hypobromite, and subsequent diffusion takes place only very slowly if the instrument is allowed to stand quietly. Experiment showed at once that agitation after the introduction of the urea solution gave very rapid reaction.

TABLE 2.—UREA DETERMINATIONS WITH AGITATION OF UREOMETER, USING PURE UREA SOLUTION

	Reading	Actual Amt., mg.
1.	14.8	15
2.	15.5	15
3.	15.0	15
4.	14.6	15
5.	15.0	15
6.	15.7	15

Readings taken in five minutes. Figures express milligrams of urea per cubic centimeter of solution.

Several consecutive determinations made with the same ureometer, No. 3 above, gave the following results: 15.1, 15.1, 15.2, 15.1, 15.0.

Agitation was brought about either by gently but rapidly shaking the instrument after the first vigorous reaction was over, or by inserting a coiled copper wire into the hypobromite tube to act as stirrer. With the ordinary shape of the ureometer, the latter method is awkward, and the shaking is preferable. The rate of reaction appears to be roughly proportional to the rate of vibration attained in the shaking. It was found that after five minutes of rapid shaking (from 250 to 300 vibrations per minute), a reading could be taken which did not increase more than 0.2 or 0.3 mg. per cubic centimeter in twenty-four hours. Furthermore, this reading was approximately correct for urea solution, as shown in Table 2.

---

[1] Folin: Ztschr. f. physiol. Chem., 1901, xxxii, 504; 1902, xxxvi, 333, and 1903, xxxvii, 548. Hawk: Practical Physiological Chemistry, p. 394. Folin and Pettibone: Jour. Biol. Chem., 1912, xi, 507. Marshall: Jour. Biol. Chem., 1913, xiv, 283.

[2] Jour. Biol. Chem., 1913, xiv, 283.

It would seem, therefore, that any one instrument gives fairly constant results with this technic, which was certainly not true when the instrument was left standing quietly. It would seem also that the largest factor in the deviation from the true value with pure urea solutions is the imperfection in the graduation of the instruments, which suggests that a correction table could be made for each ureometer, which would add greatly to the accuracy of the determinations. Our uncorrected instruments gave readings ranging from 97 to 105 per cent. of the correct value.

TABLE 3.—COMPARATIVE RESULTS OF THE DETERMINATION OF UREA BY THE DOREMUS-HINDS UREOMETER, AND BY FOLIN AND PETTIBONE'S PHOSPHORIC ACID METHOD

No. of Sample	Doremus-Hinds Ureometer	Method of Folin and Pettibone	Factor for Correction of 1	1 Corrected by Average Factor 0.917

39.	20.6	18.60	0.9029	18.89=101.5%
40.	18.5	17.28	0.9340	16.96= 98.2%

Expressed in milligrams urea per cubic centimeter.
Average factor 0.9172.

Even with pure urea solutions, it was found that if agitation of the ureometer was delayed for some time after the solution had been introduced into the hypobromite, too low results were obtained, the deviation increasing with the length of the delay. It has long been known that urea in the presence of alkali is slowly changed to cyanate, which does not decompose with hypobromite, and this doubtless explains why, when the instruments are left standing, the readings often do not reach so high a figure as with the immediate shaking.

When application of this technic was made to urine, it was found that constant results could be obtained with any one instrument, that different instruments varied slightly, as was to be expected, but that the results were invariably higher than those obtained with the accurate method of Folin and Pettibone. It has been shown repeatedly that other nitrogenous constituents of urine besides urea, especially creatinin, uric acid and guanin, are decomposed by hypobromite, with the evolution of nitrogen, and that the hypobromite itself yields slight amounts of oxygen, which facts account for the high readings. Some of these results are shown in Table 3.

Column 3 of Table 3 shows the factor by which the result shown in Column 1 must be multiplied in each case to obtain the correct value for urea, shown in Column 2. The average of these factors in the forty determinations is 0.9172. It is proposed, therefore, that the figures obtained by the use of the ureometer, the instrument having been shaken as previously mentioned, should be multiplied by this average factor as a correction. The result of this correction applied to the forty determinations is shown in Column 4, with a comparison, expressed in percentage, of this corrected value with the true value. It is seen that all but four of the forty determinations, or 90 per cent. of them, fall within 5 per cent. of the correct figure, while all but twelve, or 70 per cent. of them, fall within 3 per cent. of the correct figure.

It is interesting to note that Ekecrantz and Erikson[3] suggest that in the determination of urea by decomposition (with nitrous acid?), with subsequent measurement of the nitrogen, the results, which were found to be high, should be multiplied by the factor 0.926, obtained by averaging the error in a large number of determinations.

One of us (Robinson) has observed over five hundred urinalyses in which the total nitrogen was determined accurately by the Kjeldahl method, and the urea more or less approximately by the Doremus-Hinds ureometer. By these determinations, the urea nitrogen averaged only about 70 per cent. of the total, whereas careful analyses have shown that the urea nitrogen averages actually about 87 per cent. of the total in normal urines. This indicates that the ureometer as ordinarily used, gives results which average only 80 per cent. of the correct values, and at the same time they vary with extreme inconsistency. It is apparent, then, that the results we have obtained show a vast improvement over the usual way of performing the urea determination, and if similar results can be constantly obtained by further experience with the technic herein employed, the method may yet be rescued from the mire of disrepute into which it has fallen, and take its place as a really approximate "approximate method" in clinical analysis.

To recapitulate, it is definitely shown that the Doremus-Hinds hypobromite method for the determination of urea in urine gives inconsistent and completely unreliable results when performed in the usual way described in the text-books, but when the ureometer is gently but rapidly shaken, either by hand or by machine, at the rate of from 200 to 300 vibrations per minute, the reaction is practically completed in five minutes, and constant results are obtained with any one instrument, there being slight variations in the graduations of different instruments. These results are higher than the correct value for urea, but when multiplied by the factor 0.917, the product represents approximately the true value for urea, being within 5 per cent. of correct in 90 per cent. of the analyses made.

It should be said that all experiments thus far made have been with normal urines. In a series of examinations of pathologic urines now in progress in this laboratory, check determinations are being made of urea by the Folin-Pettibone phosphoric acid method, and the Doremus-Hinds hypobromite method, using the modified technic described above.

AN ETIOLOGIC STUDY OF HODGKIN'S DISEASE

SECOND NOTE *

C. H. BUNTING, M.D.
MADISON, WIS.
AND
J. L. YATES, M.D.
MILWAUKEE, WIS.

In a preliminary note recently published,[1] we reported that by repeated injection of the diphtheroid organism cultivated by us from cases of Hodgkin's disease, there had been produced in monkeys lesions of the lymph-nodes showing all the essential features of early Hodgkin's disease in man. Up to that time we had been unable to demonstrate that the organism could survive in the monkey for any great length of time, and therefore we felt that we could not assert that we had produced Hodgkin's disease in the monkey, or that we had even demonstrated any great pathogenicity of the diphtheroid organism for that species.

Since making that report, however, the course of our experimental work has demonstrated fully the pathogenicity of the culture we were using, and has further shown that the virulence of the organism to the monkey may easily be increased even to the point of producing death of the animal after a relatively acute illness. While the histologic picture of the enlarged lymph-nodes of the monkey taken three months after the successful inoculation, leaves no question as to the relation of the lesion to that of human Hodgkin's disease of the same duration, the great difficulty seems to be to secure infection and at the same time to avoid so great virulence as to produce extensive necrosis and softening and even suppuration. The working space between these two limits seems very narrow.

Extensive necrosis and leukocytic infiltration of the glands may seem foreign to the usual chronic picture of the lymph-nodes in Hodgkin's disease, yet a recent clinical case has demonstrated that even in man the virulence of the organism may be such as to lead to these features. With an apparent duration of six months, there is in this case marked involvement of cervical, axillary and mediastinal glands, febrile reaction and leukocytosis (44,000). While the excised glands show all the elements of well-developed Hodgkin's disease, there are, in addition, extensive areas of necrosis, softening and leukocytic infiltration. Yet culturally, the diphtheroid organism, which was obtained from both cervical and axillary glands, was the only organism to grow.

At present, our results indicate that the survival of an animal for the requisite length of time is all that is needed for a demonstration of the chronic lymph-node picture seen in the well-developed case of Hodgkin's disease.

Thus, since our experiments demonstrate that the diphtheroid organism is pathogenic for the monkey, that it produces a progressive enlargement of the lymph-nodes, with lesions similar to those of Hodgkin's disease in man, and further that the blood-changes in the monkey are similar to those in man, we feel fully assured of the etiologic relationship of the diphtheroid organism (*Bacterium hodgkini*) to Hodgkin's disease.

The experiments which have led to this conclusion are in outline as follows:

Monkey 1 (covered by previous note).—Repeated injections with diphtheroid organism between April 19 and June 30, 1913, with production of a chronic lymphadenitis, characteristic of early Hodgkin's disease. July 6, excision of glands for histologic study. Implantation of portion of gland into right axilla of Monkey A3.

Death of Monkey 1 from intussusception occurred before infection was secured.

Monkey A3.—Female rhesus.

July 6, 1913, lymph-nodes all small, shot-like. Under ether, tissue from Monkey 1, made up of parts of three lymph-nodes, introduced into axillary space. Fascia and skin closed by separate sutures.

July 9, skin wound slightly pulled apart, but clean. Fascial sutures holding well.

July 19, wound cleanly healed. A group of enlarged glands palpable in right axilla.

August 4, three enlarged glands still palpable in right axilla.

September 24, animal found dead, having died during night after gradual decline.

Post-mortem examination showed in right axilla a group of enlarged lymph-nodes, from 10 to 15 mm. in diameter, with softened areas from which, on incision, a thick puriform necrotic material was expressed. Extending upward from these nodes was a suppurative process reaching to the highest point in the axilla and involving the chest wall. The organs showed multiple metastatic abscesses in lung, heart, liver and pancreas. A hyperemic splenic tumor and cloudy swelling of the viscera were present.

Histologically, while the areas of necrosis and leukocytic infiltration were the most prominent feature of the picture in the adjacent parts of the nodes, there were all the elements of the Hodgkin's picture: distortion and disappearance of architecture; great proliferation of endothelioid cells, with marked development of endothelioid giant-cells, in some places with lobed nuclei, and proliferation of fibroblasts with both fine and patchy sclerosis. Eosinophil cells were found only occasionally (apparently due to exhaustion of the marrow as indicated by marrow sections).

The spleen showed a hyperemic tumor, pulp and sinuses being filled with red blood-cells. In addition the malpighian corpuscles showed a lesion distinct from the usual hyperplasia which results in a sharp outlining of the germinal center and a thick collar of lymphocytes. In this spleen, however, there was irregular and extensive proliferation of the endothelioid cells, with numerous mitotic figures present. Many of the cells were of the size and character of the endothelioid giant-cells in the lymph-nodes. There was also some fibroblastic proliferation in and adjacent to the corpuscles. A scattering of eosinophils was seen.

At the post-mortem examination, a culture was taken from the axillary lymph-nodes, and a pure culture of the diphtheroid organism was obtained. This grew very feebly for several generations but finally acquired greater power of growth. *This culture was used in inoculating Monkey 3.*

Monkey 3.—Female rhesus. Received April 11. Negative to von Pirquet test. April 26, first injection of two slants of a twenty-four-hour growth of culture X. F. A. subcutaneously into right thigh. Subsequent to this and up to August 17, ten injections of the same organism were made in the same location, and with the uniform result of the development of

induration and glandular enlargement which subsided gradually On one occasion June 21, inoculation resulted in the formation of a subcutaneous abscess from which the diphtheroid organism was recovered in pure culture This was subsequently used for inoculation in the hope that it might have acquired some increased virulence

October 25, there were but shot like glands in the right groin and it was felt that the animal was refractory to the culture

October 31, inoculation was made into the right axilla of the scrapings in salt solution of 3 slants of an almost invisible growth on egg medium of the diphtheroid organism recovered from Monkey 3 The salt solution suspension appeared almost clear There was no immediate sharp glandular reaction and one week later no sign of reaction along needle track

December 6 there was a large lobulated, indurated mass along pectoral edge and extending high in axilla, and consisting of enlarged glands distinct in outline but with connecting sclerosis The lower glands were over 1 cm in diameter, while high up in the axilla the glands appeared about 5 mm in diameter At the most prominent low point was a softened area with discharging sinus The material discharged on pressure was a thick white material resembling broken down glands

December 19 the wound was still discharging, and in the left axilla was an infected skin wound (apparently self inoculation) with several enlarged lymph nodes palpable above it

December 31, a second softened area appeared in the right axilla about 3 cm above the first

MONKEY 2—Male rhesus, received from New York April 11 April 19 the first injection of a twenty four hour slant growth of the culture X F A was made into the right tonsillar region When it was found that the enlargement of the cervical glands that resulted did not persist, the place of injection was changed to the cervical subcutaneous tissue, on account of the difficulty of reaching the tonsil without etherization Three injections were made in the neck region Then on June 30 the place of inoculation was changed to the right axilla Here six injections were given the dose being increased, until on August 17 four slants of a twenty four hour growth were injected The intervening injections had resulted in the development of axillary induration, associated with glandular swelling which had persisted for about a week after the injection After August 17 no injections were given On September 15 a moderate enlargement of the right axillary glands was noted This continued and on November 1 there was in the right axilla a large, lobulated mass roughly 2 5 by 3 cm in diameter, apparently made of five or six discrete glands with a certain amount of interglandular sclerosis

November 23, under cocain, a gland was removed, cultures made, tissue fixed for study, and a portion of the gland implanted in Monkey A4

Macroscopically the gland showed large, opaque, softened, necrotic areas, surrounded by more translucent hyperplastic tissue The softened material had the consistency neither of true pus nor of tuberculous caseation

Histologically, the gland showed areas of necrosis infiltrated by leukocytes There was some scarring of the gland Outside of the necrotic areas the architecture of the gland was lost The tissue was cellular, showing relatively few lymphocytes, but large numbers of endothelioid cells, many of which had very large nuclei, of the giant cell type Eosinophilic infiltration was present and marked in some areas There was a periglandular sclerosis

One nucleated red blood cell to 500 white blood cells noted October 28, 1 November 14, and 2 to 500 December 31

A pure culture of the diphtheroid organism was found in one serum tube on which a piece of gland was planted

December 6, the wound was perfectly healed, but an area of softening had developed at some distance from the wound and at the lowermost prominent point of the enlarged mass

December 26, the skin was found necrotic at one point over this area, and a thick necrotic material exuded on pressure A diphtheroid organism was found in smears from this material

December 31, skin sinus appeared healed and dry. No further softening

MONKEY A4—Large male rhesus

November 23, right axilla shows only small shot like glands high up Under cocain anesthesia, a piece of gland from Monkey A2 was implanted in the right axilla. Fascia and skin were stitched separately

December 6, wound was found perfectly healed Several moderately enlarged glands were felt above site of implantation

December 19, several enlarged glands in axilla formed a mass roughly 2 cm in diameter.

THE CORRECTION OF THE FIXED STRUCTURAL TYPE OF SPINAL LATERAL CURVATURE *

ROLAND O MEISENBACH, M D.
BUFFALO N. Y.

INTRODUCTION

Notwithstanding the fact that in the past so much has been written with regard to the treatment of the fixed structural type of spinal lateral curvature, it has generally been conceded that little progress has been made and that the results obtained have been far from satisfactory It has been generally recognized, indeed, that patients with bony rotation could not be anatomically straightened, and in selected cases only could they be improved.

Many theories concerning the mechanism of the spine have been advanced at different times, but with little or no result so far as the correction of the spine is concerned, and not more than a year or so ago it was generally recognized by all who tried to treat the fixed types of scoliosis that little or no headway toward remedying the condition could be made. Even though the contour of the trunk had been changed after a number of years of constant treatment, the radiograph still showed not only that forward rotation of the vertebrae had not been accomplished, but also that the correction, if any, was due to the changing of the contour of the ribs. The mechanism of the spine was considered very intricate by many of the writers, among whom there existed a controversy on some of the essential points of its mechanism. The diligent work done by many, however, has led (even though by means of elimination) to a better understanding of the mechanics of the spine and has evolved a new principle with respect to the treatment of the fixed structural types of lateral curvature. The results obtained to-day in structural cases with bony deformity would have been considered unbelievable a few years ago, especially that the vertebrae can be rotated, the conformation of the ribs changed and a deformed trunk made to assume the position of the normal trunk; not only may the displacement of the viscera be corrected, but also actual bony changes can be caused. Abbott has given us new inspiration to attack cases which formerly were considered impossible, and his theory has been backed by the results obtained in his work, which are demonstrated not only by the altered external contour, but through verification of the change of contour as shown by the radiogram.

MECHANICS OF THE SPINE AND EXPERIMENTS ON THE CADAVER

For the purpose of thoroughly studying the spinal movements irrespective of curves, and obtaining a better understanding of the movement of the normal spine, the cadaver was used. The object of the work was not to produce lateral curvature, but to put into practice the two methods of treatment which have been so frequently written of, namely, the method of hyperextension and the method of flexion, the latter being practically Abbott's method. The questions immediately arose in my mind: Is it possible to rotate the vertebrae in the dorsal and lumbar regions with the spine hyperextended? Is it possible to obtain more motion and more rotation in the dorsal and lumbar region with the spine in flexion? What is the effect of side bending in regard to hyperextension and flexion?

Since performing the experiments in which roentgenograms of the cadaver in the different positions were made, a much better understanding has been afforded me and many doubtful problems have been solved to my satisfaction. The cadaver in an upright position was firmly anchored at the pelvis; an iron pipe was crossed anteriorly and anchored at the shoulders for the purpose of controlling rotation; long hatpins were driven into the spinous processes and numbered; the cadaver was placed in eighteen different positions and records made, after which roentgenograms of it in different positions were made, from which the following conclusions were arrived at:

CONCLUSIONS DRAWN FROM EXPERIMENTS ON THE CADAVER

That forward traction of the spine opens the articulations and unlocks the spine. Hyperextension locks the spine, most in the lumbar region and somewhat in the dorsal. At the junction of the twelfth vertebra there is a weak spot, which allows some rotation, but the twelfth vertebra follows the action of the lumbar vertebrae rather than the dorsal. Forward traction and side bending with rotation places the spine in the most favorable position for complete freedom of all the vertebrae.

TREATMENT

In considering the treatment, as previously remarked, the spine itself is not the prime factor, but the trunk as a whole must be considered. Only within the last two years has it been shown that in many of the fixed structural types patients can be completely straightened and, in the severer types, benefited both with regard to the deformity and especially to the general health; but it is necessary to consider not only the bony structures, but also the clinical entities relative to the viscera. I have been impressed by this fact in some of the far-reaching and excellent results that have been obtained in many patients after a comparatively short treatment, and even before the treatment has been entirely completed.

Since the flexion treatment has given such excellent results in a comparatively short time, those of us who have much to do with these cases which were formerly considered hopeless, or in which, at best, it was only possible to prevent the deformity from growing worse, thus consider that a new epoch has been entered on in the treatment of the fixed types of lateral curvature. This is proved by the fact that many of the patients now being treated, and in whom marked improvement has been noted, had previously received various treatments over periods of from two to ten years, but had not been corrected anatomically, nor had the spine actually been unrotated or the deformity been entirely corrected. Figures 11, 12, 13, 15, 16 and 19 very well illustrate these statements.

In considering the treatment of any given case, there are several procedures necessary so that the operator will not deceive himself as time passes, but may be able to refer to accurate records in connection with the case.

1. A thorough physical examination of the chest, to determine the condition of the heart and the lungs, with a blood-pressure or any other test or chemical analysis which the internist may deem necessary.

2. Thorough and accurate measurements with the scoliometer (Fig. 8) and records of the general posture and contour of the chest at any given level of the trunk.

3. Satisfactory roentgenograms before treatment is begun and through the cast during the process of correction. For this purpose I have devised a scoliometer and Roentgen-ray equipment.

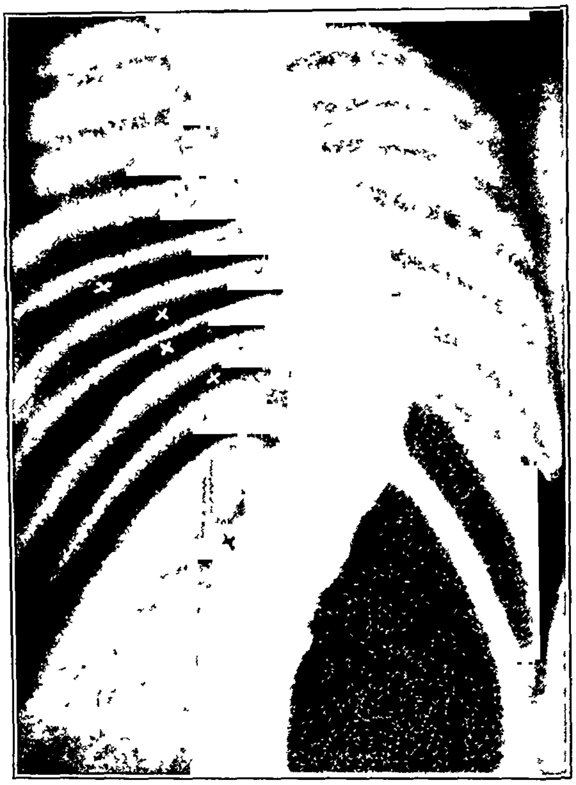

Fig 13—Roentgenogram taken in Case 5 before flexion treatment began Note rotation of dorsal and lumbar vertebrae, also asymmetry of ribs

The treatment of the structural type heretofore has been chiefly what I prefer to call the hyperextension treatment, or the treatment of Wullstein, by traction and hyperextension. I have always believed it unsatisfactory, and because until recently I have felt a certain amount of hesitation with regard to these cases I have refrained from speaking or writing of this type.

In view of the gratifying results which we have obtained after much study, experimenting and work in the very cases which formerly could not be successfully treated, this paper seems justified. The new treatment is practically flexion treatment, in which the spine is unlocked, the ribs are rotated and lateral traction is applied, after which the trunk is fixed with a plaster dressing. Aside from the discomfort occasioned by the wearing of the plaster jacket, comparatively little pain has been encountered, and this is attributed to the method of procedure.

RECORDING SPINAL CURVATURE AND THE DEFORMITY OF THE TRUNK—MENSURATION

After the patient has been carefully examined, both by the orthopedist and the internist, or the family physician, careful records of the case should be made. The patient should be placed in an accurate scoliometer; the general contour of the thorax and the distortion of the ribs, together with the general poise of the pelvis, should be recorded. The lateral deviation of the spine and the angles of the scapulae should be marked with India ink and photographed through a graduated screen (Figs. 11, 12, 15 and 16). With a carefully constructed scoliometer, the personal equation will be minimized and a thorough reading of the records is obtainable many months after the case has been recorded. The record taken by the scoliometer gives not only the contour of the thorax and the distortion of the ribs, but also the lateral deviation of the spine and the relation of the trunk at a given level to the pelvis.

I have described[1] the scoliometer at length, and have suggested a pelvithoracic triangle, which records the pelvic and any other cross-section of the trunk.

RECORDING BY MEANS OF ROENTGENOSCOPY

Roentgenoscopy has been advanced to such a degree that we can now hardly dispense with it whenever any question of deformity arises. It is becoming more and more standardized, and if the same apparatus is used each time it becomes a very valuable and accurate method of observing the spine. Especially is this true with regard to the condition of the lateral curve and rotation, as it shows the difference in the lumbar and dorsal rotation, as well as the displacement of the heart, diaphragm and, if one wishes, the stomach and intestines.

It has been said by some writers that they do not believe in roentgenoscopy relative to lateral curvature. This may be due to the fact that they either have not the equipment or do not wish to expend the energy and expense that is required to undertake this procedure.

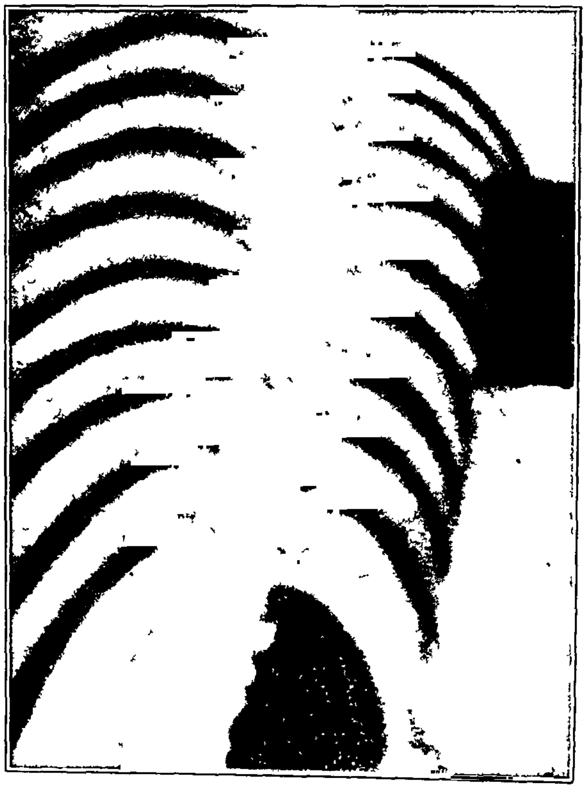

Fig 14—Roentgenogram taken in Case 5 after sixteen weeks' flexion treatment Compare with Figure 13, noting position of spine and separation of ribs

The comparative value of these records is clearly shown in Figures 13, 14, 19 and 20. It is commonly known that the spinous processes in lateral curvature do not give a true clinical indication of the actual condition of the spine. The spine is usually very much more curved than the casual examination of the patient indicates. This is due to the fact that the rotated bodies lie deeper and more to the convexity of the curve than the spinous processes do. Also, the spinous processes vary in length in different persons. This naturally is deceptive and must be guarded against by the orthopedist. It may also be easily recognized from the roentgenograms that the contour of the ribs changes. On the convex side usually we have sharp angular ribs, and on the concave side depressed, flat, adjoined ribs. After the first corrective jacket has been applied, the ribs on the concave side usually will show a tendency to separate and to assume a curved form, and conversely those on the convex side rotate and become less prominent. This can be observed only by means of roentgenoscopy.

---

[1] Meisenbach, R O: Am Jour Orthop Surg, May, 1912

The patient is placed prone with or without the jacket. If the jacket is worn the roentgenoscope is slightly elevated to permit the photographic plate to pass beneath, so that the patient does not rest on the plate proper, but is suspended by the canvas stretcher (Fig. 9). The Roentgen-ray tube is placed in the median line and directly above the patient. The exposure may be made directly through the plaster jacket. Unless the spine, during the process of correction, is roentgenographed through the plaster jacket it will be difficult to arrange the padding satisfactorily and comprehensively; also, it will be difficult, or well-nigh impossible, to have a thorough understanding with regard to cutting the windows (Fig. 20) in the corrective jacket, which is most essential in the flexion treatment (Fig. 20).

Space will not permit the details of each procedure. If the method is pursued as described one can almost exactly state the amount of gain that is being accomplished; the position of the spine will at all times be known to the operator, and when the next jacket is to be applied the roentgenogram will be of great assistance to him in indicating the amount and position of the pressure and traction to be applied.

CORRECTING THE DEFORMITY AND THE LATERAL CURVATURE

After thorough study of the patient with the records which have been made, the patient should be placed in the most favorable condition for correction, as is the case in any procedure in which manipulation is to be undertaken. In the cases in which cardiac involvement is present, extreme precaution should be taken. Psychically, they should be placed in a hopeful frame of mind, and should not go to the operating-room without being sufficiently nourished. It has been my custom to secure perfect quiet on the part of the patient during the night before applying the first corrective jacket, also to explain freely to the patient the modus operandi, so that the sight of the complicated apparatus will not change the blood-pressure or pulse rate. The nurses and assistants should be well trained in team-work, so that the patient will be in the frame only a minimum time. After the patient is in the frame the procedure should continue uninterruptedly, and just before the tractions have been applied the Roentgen-ray tube should be applied over the patient with careful study with regard to the anatomic landmarks. In compound curves this is more essential than in total curves, as in the compound curves one may do much harm, especially after the second jacket has been applied. It is my rule to throw compound curves into total curves and then to correct the total curve rather than to attempt to correct both curves. In some compound curves the dorsal convexity can be corrected by correcting the dorsal curve, allowing the lumbar curve to adjust itself. This has been my experience in a few instances.

After the jacket is applied, the patient is placed face down on the truck, which has previously been heaped with pillows. The Roentgen ray should again be used at the time of cutting the posterior window. Those patients in whom there is a complication of heart disease should remain in bed for a day at least.

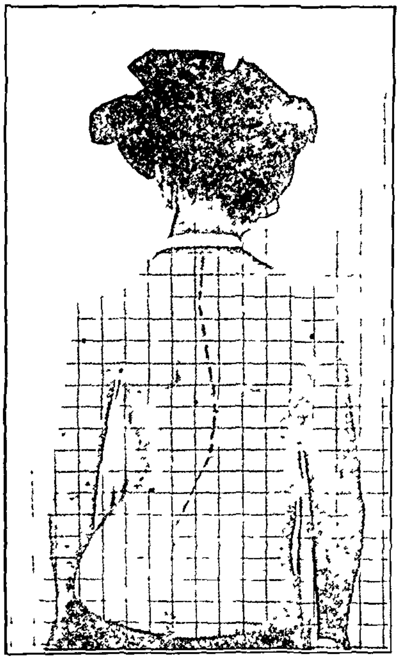

Fig. 15.—Photograph taken in Case 6 after one and one-half years' treatment by various methods.

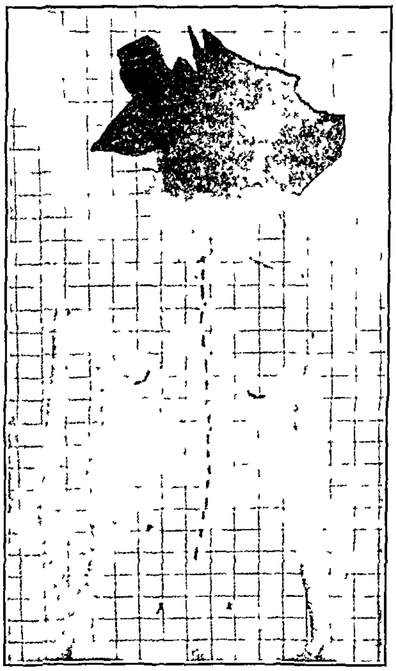

Fig. 16.—Photograph taken in Case 6 after seven weeks' flexion treatment. Note the change in trunk.

RESULTS OBTAINED

The question immediately arises: Shall we attempt to correct the severe types which are so frequently seen, those in which the spine is so curved and rotation so marked that the ribs have been forced into the iliac fossae, or in which the heart has been so displaced and the nerves so deranged as to cause the patient to be most apathetic and fretful? Many of these persons, either through experience or through the medical profession, have learned that their cases are probably hopeless; therefore, they look on any procedure with skepticism. I firmly believe that even in the severer cases, except in those in which the deformity is in the cervical region, the flexion treatment should be used, with a view to raising the ribs, increasing excursion and benefiting the general health, rather than to making the actual anatomic correction.

RECAPITULATION

1. The chief causative factors of scoliosis are muscular weakening, together with the anatomical construc-

tion of the torso. A lateral curve may be considered as a sequence rather than as a primary entity. It may be induced in many ways, through disease, posture, congenital defects or variation of the bony skeleton.

2. There are practically two types of backs, the flat and the lordotic. Each of these, occurring in children, must, according to Wolff's law, affect the anatomy of the torso.

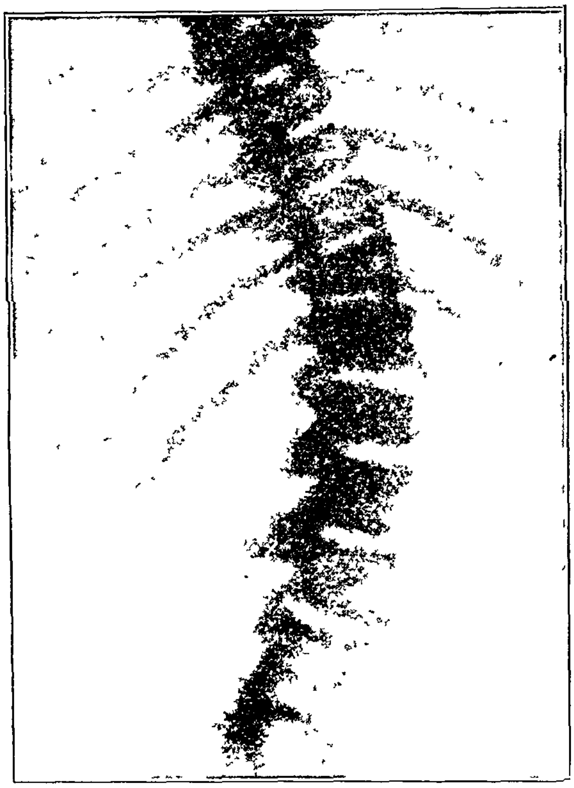

Fig 19.—Roentgenogram taken in Case 6 before flexion treatment began Note rotation in dorsal and lumbar vertebrae. Rotation in lumbar vertebrae almost one quarter round

3. The spinal action is closely allied to the anatomic construction, as is shown by the articular processes of the twelfth dorsal, the dorsal and the lumbar vertebrae.

4. Experiments on the cadaver, both with and without the Roentgen ray, show that hyperextension locks and flexion unlocks the spine; that in hyperextension the lumbar spine is completely locked, whereas the dorsal is only partially locked and admits some rotation. In forward flexion and side bending the spine is in the best position for correction and for the rerotating of a lateral curve.

5. There are three types of scoliosis, the congenital, postural and structural. The structural is the most difficult to treat, as it involves the consideration not only of the spine, but also of the viscera of the torso, and the general condition of the patient. In the fixed structural type the ribs and vertebrae have become deformed, the ligaments have contracted and the viscera are displaced. The postural type is a forerunner of the organic, and if left alone will cause bony changes and therefore should receive attention early.

6. In considering any case for treatment, complete records of the case should be made by means of special apparatus (the scoliometer), the anatomy of the patient should be studied by means of roentgenograms and the patient thoroughly gone over by the internist or the family physician. If this is done, the risk to the patient will be minimized, even in the severer types. The displacement of the heart, with heart-murmurs, together with symptoms of anemia or gastric disturbance, are not necessarily contra-indications for treatment, but it is often the case that these conditions and symptoms improve after the spinal correction has been undertaken. In some cases the percentage of hemoglobin is increased after correction. It is a common occurrence in patients afflicted with scoliosis and lack of excursion of the ribs to find suboxygenation resulting from the deformity. The excursion of the ribs can best be improved by the correction of the spinal deformity.

7. Since it has been proved that the spine can actually be rerotated and the deformed ribs remodeled, as it were, many of the cases which were formerly considered hopeless may now be much improved and straightened.

8. Persons with extreme scoliosis may be very much improved in regard both to the general health and to the deformity, and, therefore, should receive a careful consideration. The mild types, and even those which formerly were considered beyond help may now be anatomically corrected when skilfully treated.

9. The new method of treatment is comparatively rapid, and in some instances surprisingly rapid, when compared with the old methods, and pain is not necessarily in proportion to the deformity, but its absence in the process of correction depends much on the technic.

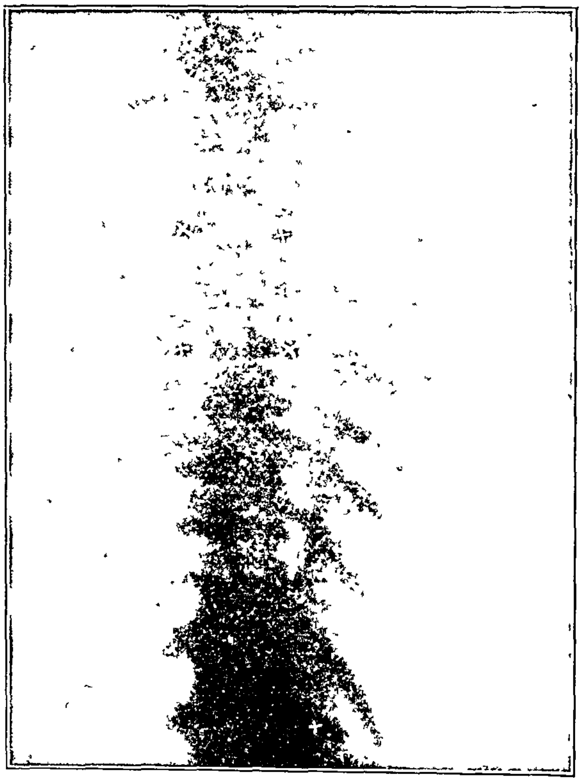

Fig 20.—Roentgenogram taken through plaster jacket in Case 6 seven weeks after correction. Window in jacket plainly seen. Spine is straight; vertebrae rerotated. Position of padding to be added is easily determined by means of such roentgenograms.

10. It is the duty of every practicing physician to look carefully over any doubtful cases which may suggest flatfoot, or any irregularity in posture, because these deviations from the normal may be forerunners of lateral curvature and, later on, of a severe deformity of the spine.

ABSTRACT OF DISCUSSION

Dr. John L. Porter, Chicago: Dr. Meisenbach seems to be working out the same problem that all of us are concerned with in scoliosis, trying to find the best method of technic for carrying out the ideas that Dr. E. G. Abbott of Portland, Me., gave us. Dr. Abbott told me that he learned something every time he put on a new cast. I find that characteristic of my own work. I have treated fifty-seven cases by the Abbott method, and have not put on any two jackets alike. I have learned something new every time I put one on. The great function of the Committee on Scoliosis of the American Orthopedic Association is to help us to standardize our methods of recording indications and of analyzing and sifting what little we all learn, as we try to do this work.

HYGROMA CYSTICUM COLLI AND HYGROMA AXILLARE *

OLIVER C. SMITH, M.D.
Surgeon to the Hartford Hospital
HARTFORD, CONN.

Case 1.—*History.*—My first case of hygroma cysticum colli, or at least the first one in which the condition was recognized, occurred in J. R., aged 12, of Winsted, the patient being referred to me by Dr. David Reidy. The family history was irrelevant. The patient had pneumonia at 9 and meningitis at 18 months. At 2½ years a swelling in the left cervical region was noticed; at 10 years, following a blow by a snowball, the growth enlarged more rapidly. He was a well-developed, wholesome-looking, normal boy of good color. The physical examination was practically negative, except that a large cystic tumor existed in the left cervical region, extending from the lobe of the ear nearly to the clavicle (Fig. 1). There were no enlarged lymph-nodes. Diagnosis: cyst of undetermined character.

Operation.—July 31, 1911, at the Charter Oak Hospital, a curved incision was made just below the ear downward, forward and upward, the flap dissected and a thin-walled multilocular cyst exposed. The anterior jugular vein was ligated, and the branches of the facial nerve exposed and protected. The cyst was found intimately connected with the parotid gland, its upper attachments being in close proximity to the styloid process, and was removed intact. It contained a clear, watery fluid. The wound healed primarily, and there has been no recurrence.

Pathologic Report (by Dr. Henry C. Russ).—Macroscopic Examination: Specimen consists of a collapsed cyst from the neck, the contents having escaped. The cyst measures 7 by 3.5 cm.; its wall is tough and fibrous, though quite thin. The cavity is lined by a shiny membrane. The inner wall is much trabeculated and shows numerous pouches of varying size communicating with the main cavity, giving the whole a very multilocular appearance.

Histologic Examination: The membrane lining the cyst is composed of flattened endothelial cells arranged in a single layer. The wall outside is made up of fibrous tissue and fat. In the fibrous tissue are numerous capillary blood-vessels and lymph-spaces, the latter varying much in size, some being large enough to merit the name of small cysts. Scattered also in the fibrous tissue are numerous small areas of lymphoid cells. Surrounding the main cyst cavity in a narrow zone are small bundles of fibers morphologically like smooth muscle cells (Figs. 2 and 3).

Case 2.—*History.*—The second case, in a man aged 20, a student, referred by Dr. A. E. Abrams, came under our observation July 15, 1913. The family history is irrelevant. The patient has never been seriously ill. In September, 1912, he noticed a tumor in the left axilla which has grown steadily and is of large size; is soft, not movable or tender. He is a good-sized, well-nourished, wholesome-looking boy with practically negative physical examination, except a large, fluctuating, oblong-shaped tumor in the right axillary space extending below the nipple line, 15 cm. in length and 8 cm. in breadth. Diagnosis: hygroma cysticum axillare.

Operation.—July 15, 1913, at the Hartford Hospital, a vertical incision was made over the tumor. When the skin and fascia were incised a very thin-walled multilocular cyst tensely distended with watery fluid was exposed and readily dissected from its upper attachments under the clavicle to its lower extremity at the eighth rib. From 250 to 300 c.c. of fluid were contained in the various compartments of the cyst. The incision was closed without drainage. A hematoma formed which delayed somewhat the process of repair. Recovery, however, was satisfactory, the wound healing kindly. Up to the present there has been no recurrence.

Pathologic Report (by Dr. John Carter Rowley).—Macroscopic Examination: A sac of thin tissue 10 cm. long and 4 cm. in diameter. The walls of the sac are very thin and grossly present no abnormal structure. Specimen shows two lymph-nodes, fat and tissue, and apparent remains of cyst wall lined with endothelial cells.

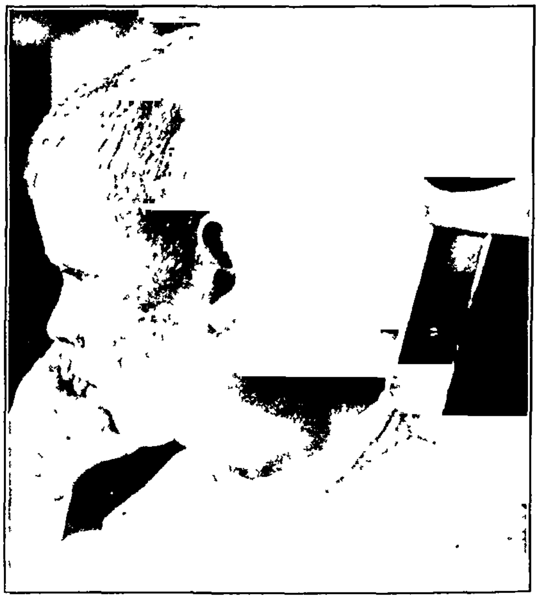

Fig. 1.—Patient (Case 1) with hygroma cysticum colli.

Case 3.—*History.*—Since the two preceding cases were reported a third case of hygroma cysticum has come to my notice. The patient (Fig. 4) was operated on by Dr. Arthur M. Rowley, visiting surgeon at the Hartford Hospital, by whose kind permission I am allowed to report it at this time. The operation was performed Oct. 7, 1913. The patient, a girl baby, R. M., aged 14 days, referred by Dr. H. J. Onderdonk, East Hartford, Conn., was delivered instrumentally without untoward incident and is breast-fed. At the time of birth a swelling in the left axilla the size of an English walnut was observed. The mass grew rapidly, extending downward.

Physical Examination.—The child is healthy looking, of normal size and good nutrition, with skin and mucous membranes of good color. Examination of lungs, heart and abdomen is negative. The fontanels are flat, not enlarged. There is no epiphyseal enlargement of long bones. Extending from clavicle to 2.5 cm. below the left nipple, and from midclavicular line to slightly beyond the posterior axillary line is a lobulated non-inflammatory tumor the size of a medium orange. It is slightly movable at the chest wall. The skin over it is adherent and has a few small lobules. The lobulations have no pulsations. Axillary lymph-nodes are not enlarged. There is edema of the arm. Diagnosis: hygroma cysticum axillare.

Operation.—Oct. 7, 1913, at the Hartford Hospital, under chloroform anesthesia a 10 cm. incision extending from the anterior axillary line downward and mesially over the tumor was made. A large, thin walled, multilocular cyst containing clear serous fluid arising from the fascia of the apex of the axilla and attached to the skin was removed intact. Axillary vessels were exposed, and the fascia of the pectoralis major under the tumor removed. Skin was closed with horsehair sutures without drainage. Primary union and prompt recovery followed.

---

* Read before the Surgical Section of the Hartford Medical Society, Nov. 24, 1913.

Pathologic Report (by Dr. John Carter Rowley).—Macroscopic Examination: Specimen removed from the left axilla of infant R. M. consists of a mass 5 by 8 cm. of thin-walled cysts containing clear, serous fluid. The cysts vary in size from 1 or 2 mm. to 4 cm. in diameter. The cyst walls are smooth and glistening and of a pearl color with numerous subsidiary sacs projecting from the larger ones. The walls of the cysts are of fibrous tissue with here and there strands of fat.

Histologic Examination: Section shows many cysts of various sizes in supporting structure of connective tissue. The connective tissue is very vascular with a few small areas of extravasated blood and clumps of fat-cells. The cyst walls in places are lined by a thin layer of endothelial cells. In most places this is lacking.

The literature on hygromas is meager, and the nomenclature is confusing. The term has been applied among other conditions to collections of fluid in synovial cavities and tendon sheaths, but is now rarely used to describe these conditions and is understood to mean a thin-walled, multilocular cyst containing clear fluid, lined with endothelial cells and possessing unusual tendency to grow. Such cystic growths are comparatively rare.

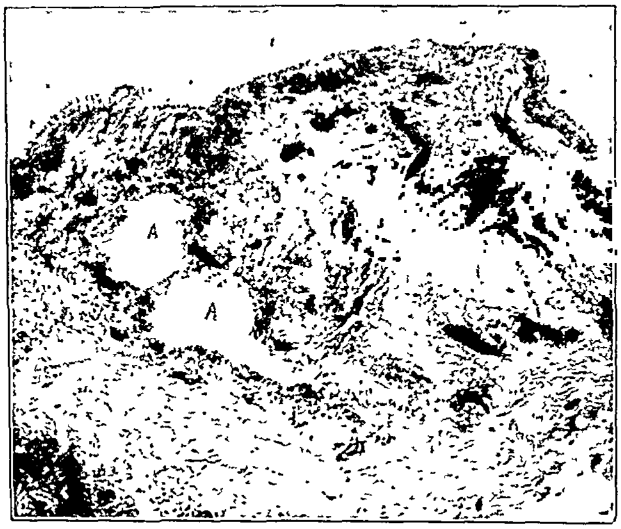

Fig. 2.—Wall of hygroma; low-power magnification. Upper margin is inner endothelium-covered wall of cyst cavity; *A*, *A*, lymph-spaces in wall of hygroma.

Dowd[1] has made a careful compilation of the statistics after a thorough search of foreign and domestic literature. Ninety-one cases of hygroma cysticum colli, thirty-five cases of hygroma cysticum axillare, and eleven cases of hygroma cysticum (general) were collected, and these were all that could be found. Adding Dowd's three cases of hygroma cysticum colli to the table which he compiled, and the two cases of hygroma cysticum colli herewith reported, brings the number up to ninety-six. Dowd's case of hygroma cysticum thoracis would bring the table of hygroma cysticum (general) up to twelve. The two cases of hygroma cysticum axillare herewith reported would bring that class up to thirty-seven.

These tumors vary in size from small affairs to enormous disfiguring growths, usually occurring in the neck and sometimes extending downward under the clavicle, penetrating the mediastinum or passing under the clavicle into the axilla or pectoral regions. They are frequently congenital and are usually seen in children. Dowd says that the most satisfactory explanation of the existence of these hygromas is that embryonic sequestrations of lymphatic tissue existed and that they had the power of persistent regular growth.

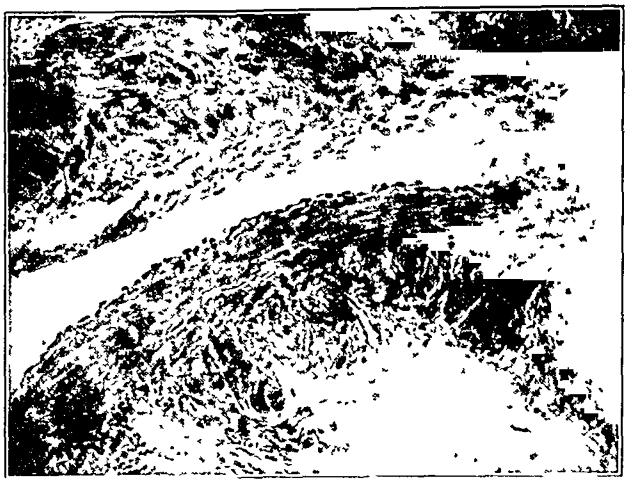

Fig. 3.—Diverticulum in wall of hygroma showing endothelial lining; high-power magnification

Adami, in his work on pathology, says that we must suppose that with increasing distention there has been a closing of the channel of which they are a dilatation; that the endothelium has grown *pari passu* with the dilatation, and that this endothelium has secretory powers. The mere force of the lymph flow cannot explain such extreme development; we have to assume active excretion, which, indeed, is indicated by many other considerations and actual experiments.

The operative rarity of these cases is responsible for incorrect diagnoses. Undoubtedly such cysts have been removed and classified as of branchial or thyroglossal origin. As they grow to enormous size they are most disfiguring and do not tend to spontaneous recovery. Their early recognition and careful dissection is important.

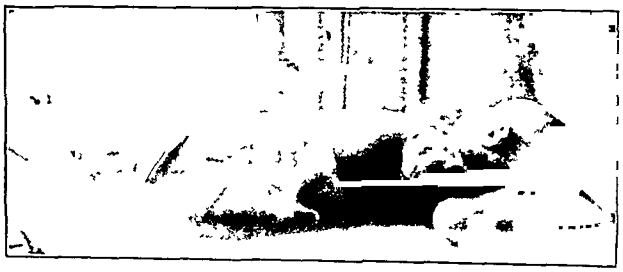

Fig. 4.—Patient (Case 3) female; aged 14 days, with hygroma cysticum axillare

I wish to express my appreciation to Dr. A. J. Wolff for the photomicrographs of Case 1, and to Drs. Henry C. Russ and John Carter Rowley for their pathologic reports.

44 High Street.

ACTION OF THE NITRITES ON THE ISOLATED SURVIVING PULMONARY ARTERY

PRELIMINARY NOTE*

DAVID I. MACHT, M.D.
Instructor in Medicine, Johns Hopkins University Medical Department
BALTIMORE

The regulating mechanism of the "lesser" or pulmonary circulation, and in particular the vasomotor control of the lungs, is a problem which for a long time engaged the attention of some of the most skilful physiologists and may still be regarded as not entirely settled. Thus, for instance, while Openchowski,[1] Knoll,[2] Brodie and Dixon,[3] and recently Baehr and Pick,[4] doubt the existence of pulmonary vasomotors, Bradford and Dean[5] declare that such fibers are found, though rather poorly developed, and François-Frank,[6] Plumier[7] and Wiggers[8] stoutly maintain the presence of an efficient pulmonary nervous control. Still less is known in regard to the action of *drugs* on the pulmonary vessels. The study of this subject was approached by two chief methods: the one by recording changes in pulmonary arterial and venous blood-pressures the other by estimating the amount of fluid perfused through the lungs. Both methods are complicated, exposed to many sources of error, and give results difficult of interpretation. Thus epinephrin, about the only drug which has been studied in this connection, is said by some to have no effect on the pulmonary vessels at all, by others to produce vasoconstriction, and by still others to cause a dilatation.

I have for some time been engaged in testing the action of various pharmacologic agents on surviving rings or strips of the pulmonary artery, a method which in the case of the lungs has never been systematically tried. This method, through eliminating all other factors present in the living body, has the advantage of being clear-cut and affording information as to the effect of drugs directly on the artery alone. Within recent years the idea has been gaining ground that a drug may possess different and even opposite actions on the blood-vessels of different organs, not in the sense of a constriction in one set of vessels causing a greater flow of blood to another region and so passively enlarging the vessels there, but in the sense of constrictor or dilator effects being *actively* induced by the drug itself. For instance, it is well known that various digitalis bodies in moderate doses will produce a constriction of the splanchnic vessels and at the same time an active dilatation of the renal arterioles,[9] and again it has been shown by Janeway and Park[10] and others that epinephrin, while being a powerful vasoconstrictor, has a dilator effect on the coronary artery. It was with the hope of possibly finding analogous conditions in the case of the pulmonary artery that the research was undertaken.

METHOD

The apparatus employed was very much the same as that used by Voegtlin and myself,[11] which is a modification of the original method of O. B. Meyer,[12] in studying the action of drugs on the coronary arteries. Rings, or more often in this research, strips of the medium-sized branches of the pulmonary arteries of pigs and oxen were used. Great care must be taken in dissecting the vessels not to overstretch or tear them. If freshly dissected and kept in Locke's solution in the ice-chest, the arteries survive two or three days or even longer. The best results, however, are obtained by using the arteries not more than twenty-four hours old. A single strip from 0.5 to 1 cm. long and from 3 to 4 mm. wide is quite sufficient to give demonstrable results.

The preparation is suspended in a small glass chamber filled with warm Locke's solution at the temperature of 37 C. (98.6 F.), through which a constant stream of oxygen is kept bubbling. One end of the arterial strip is fixed to the bottom of the chamber, while the other is connected to the short arm of a lever, the longer arm carrying a point for recording on a very slow kymograph. The glass chamber is immersed in a water-bath or jacket for regulating the temperature. Great care must be taken to keep the temperature and flow of oxygen constant.

The most difficult part of the experiment is the so-called "weighting" of the preparation, which for each kind of artery must be learned by practice. The artery when excised is in permanent contracture or "tonus," and the tonus must be overcome before its reaction to drugs can be studied. To do this a stretching load is attached to the long arm of the lever and the artery weighted or stretched until the tonus is overcome. This usually takes from fifteen to twenty minutes. After the artery has been relaxed, the stretching weight is taken off and a permanent or lifting weight is attached. Owing to the much poorer musculature of the pulmonary artery, the lifting weight was found to be much less than that required for the carotid or coronary. Whereas in case of the coronary the lifting weight is usually from three-fifths to two-thirds of the stretching weight, for the pulmonary it was found that a lifting weight which was from one-sixth to one-fourth of the stretching weight was the most suitable.

ACTION OF THE NITRITES

The action of many drugs—epinephrin, digitalin, digitonin, digitoxin, bufagin, atropin, ergotoxin and others—on the pulmonary arterial strip was tested. The effect of these different pharmacologic agents will be described in a later paper. I wish here to mention only the effect of the nitrites. The action of this group of drugs was found to be so remarkable and also of such practical interest that it was deemed worth while to describe it in this preliminary note.

Sodium nitrite, nitroglycerin, erythrol tetranitrate and amyl nitrite were each and all found to produce a *contraction* or constriction of the pulmonary arterial strip. This remarkable action of the nitrites, which have always been known as typical vasodilators, though unexpected, probably holds good in the living body too, as corroborated by some indirect evidence gathered by other observers. Bradford and Dean, observing simultaneously the blood-pressures in the carotid and pulmonary arteries of dogs, noted a rise of pulmonary pressure after administration of nitroglycerin and amyl nitrite, which they erroneously attributed to "an action on the heart in such a manner as to weaken the efficiency of the left side so as to lead to the accumulation of blood in the right side." H. C. Wood, Jr.,[13] also by the blood-pressure method, noted a rise of pulmonary pressure after amyl nitrite, which he strongly suspected as being probably due to a pulmonary vasoconstriction. To quote his words, "It would seem almost proven by exclusion that the cause of the rise of pressure in the lesser circulation can be due only to contraction of the pulmonary blood-vessels." Finally, a French observer, Petitjean,[14] studying changes in pulmonary blood-pressure, and at the same time controlling his observation "colorimetrically" by direct inspection of the exposed lungs, also noted a rise in pulmonary blood-pressure and a blanching of the lungs after the same drug. It will be seen that the observations of all these investigators would tend to speak for a vasoconstrictor action of the nitrites.

After the effect of the nitrites on the arterial strip suspended in Locke's solution had been studied, the experiment was repeated, in order to approximate more to the condition in the living animal, by suspending arterial strips in blood-serum. Here too the same effect was observed. Finally the action of the nitrites was tested on strips of human pulmonary artery obtained from a fresh necropsy, and here too a vasoconstrictor effect was observed. It may be mentioned here that if preserved in fresh Locke's solution and kept in the ice-chest, I have seen such an artery respond to drugs twenty-five days after the post-mortem.

In view of the foregoing observations, it will be seen that in causing a constriction of the pulmonary vessels and at the same time being efficient peripheral and splanchnic vasodilators, the nitrites meet the ideal requirements for therapeusis of pulmonary hemorrhage. Turning to clinical data, we find even there already some evidence of that being true. Francis Hare[15] in 1906 reported nine cases of hemoptysis successfully checked by amyl nitrite. Rouget[16] in 1905 reported ten similar cases. Grace-Calvert[17] in 1907 speaks of having employed it successfully in pulmonary hemorrhage twenty times, and a few other cases are mentioned by Colman,[18] Smith[19] and Georges Bouilard.[20]

It is to be hoped that my observations may contribute to more rational therapeusis of pulmonary conditions.

The vasomotor action of the nitrites here described is not only interesting from the practical point of view, but also raises an equally interesting question as to the physiologic and pharmacologic explanation of that phenomenon. That is a subject, however, which I shall not discuss in this place, but which I hope to touch on in the fuller paper to appear in the *Journal of Pharmacology and Experimental Therapeutics.*

Self-Preservation.—A knowledge of the laws of life is more important than any other knowledge whatever. . . . A knowledge which subserves direct self-preservation. by preventing loss of health, is of primary importance.—Herbert Spencer.

THE ENERGY INDEX

CARDIOVASCULAR ENERGY AS INDICATED BY THE ARTERIAL PRESSURE PER MINUTE

JOSEPH H. BARACH, M.D.
PITTSBURGH, PA.

Thus far we have had no reliable method for estimating the functional capacity of the heart, although much has been written on the work done along this line, nor have we a certain and easily applicable method for determining the velocity of the blood. Aside from these, we need an index to the intravascular tension and to the amount of energy which the circulatory system expends in the course of a minute, an hour or a day. We need these particularly when we are dealing with cases in which the heart or the blood-vessels are endangered.

The best means which we have at present for determining the expended energy of the circulatory system is the use of the mercury manometer. With this instrument, by the auscultatory method, we can accurately measure the arterial pressure at the time of systole and at the time of diastole of the heart. The systole gives us the energy factor in the work of the heart. The diastole gives us the energy factor in the peripheral resistance. From the pulse-rate we know how many systoles and how many diastoles to each minute there are in the arterial tree.

For example, if the maximum pressure is 120 mm. Hg, the minimum pressure 70 mm. Hg and the pulse-rate 72 per minute, the exertion in one minute would be:

In systole .... 120 mm. Hg × 72 = 8,640 mm. Hg
In diastole .... 70 mm. Hg × 72 = 5,040 mm. Hg
In both ...... 190 mm. Hg × 72 = 13,680 mm. Hg

This, according to the most practical means we have, represents the total effort exerted per minute by the cardiovascular system. We may call it the energy index or S. D. R. index.[1]

The advantages of this method of indicating the expended energy of the cardiovascular system are that we are not deceived by the high maximum pressure when it is combined with a relatively low minimum pressure, or vice versa. It is a well-established clinical fact that the two pressures do not always tend in the same direction, and that one or the other may rise or fall.

Also in this method, we do not neglect to consider the pulse-rate, which is an absolutely necessary element in properly estimating the expended energy of the cardiovascular system in a given length of time.

Judging by the clinical reports of the present day, the pulse-rate heretofore has largely been left out of this consideration. It is true that the number of pulse-beats per minute is not the greatest factor in producing high blood-pressure; but that each ventricular systole plays its part in the total blood-pressure is obvious, and that a greater number of systoles represents a greater total energy expenditure and a greater wear and tear is also clear enough. It is the last-mentioned factor particularly which we may aim at estimating in our clinical work, and for which the S. D. R. index is most useful.

---

[1] This method for obtaining an index to the cardiovascular energy is so simple that when its utility occurred to me I scarcely thought it possible that it had not been suggested long ago. In a search through the literature at my command, I have not, however, been able to find it. Certain it is that it is not a recognized method, which I believe it deserves to be.

If we were to take into consideration the duration of the systole and the diastole in every case, our calculations would be still more representative of the total cardiovascular energy. According to Tigerstedt, in the normal person the average duration of the systole is from 0.19 to 0.382 second, and the diastole is 0.4 second. But the cases in which this would be an important clinical factor are the exceptions, although with the recording instruments, the actual time of both systole and diastole can be determined readily. On the other hand, absolute values would not necessarily aid us greatly in our diagnosis, prognosis or treatment. What we need for our every-day work is an index, and a point for the normal; after that our values are just as useful, so long as they are relatively true.

How enlightening this method is may be inferred from the findings in a series of 289 young men between the ages of 15 and 30 years (Table 1). There were 41 cases in which the maximum pressure ranged between 110 and 120 mm. Hg. Ordinarily, we should pass this over without much consideration; but on comparing the extremes of cardiovascular energy in this series, and in the subsequent ones, we soon see that the maximum pressure alone, on which most reliance has heretofore been placed, gives us not even an inkling of what is going on.

TABLE 1.—TOTAL ENERGY INDEX IN TWO HUNDRED AND EIGHTY-NINE CASES

Group	Total No. Cases	Maximum Blood-Pressure mm. Hg.	Extreme Instances	Maximum	Minimum	Pulse	Total Energy Index mm. Hg. per Min.
1	41	From 110 to 120	Case A	115	52	72	12,024
			Case Z	110	88	124	24,552
2	99	From 120 to 130	Case A	124	68	68	13,056
			Case Z	125	100	120	27,120
3	76	From 130 to 140	Case A	138	90	64	14,592
			Case Z	132	118	132	33,000
4	43	From 140 to 150	Case A	142	85	60	15,436
			Case Z	148	98	120	29,520
5	26	From 150 to 160	Case A	150	90	76	18,240
			Case Z	150	115	88	27,440
6	4	From 160 to 170	Case A	164	110	68	18,632
			Case Z	162	80	120	29,040

Case A and Case Z in each group are examples of the extreme cases in that group. Whether in Case Z of each of the groups the increased activity was physiologic or not, temporary or constant, is to be determined by reexamination and by other means. That there was present at the time of the examination a marked increase of activity over Case A, and how much the increase amounts to, can be determined best by utilizing the S. D. R. index—the energy index.

In Table 2 is presented a series of 116 normal cases in which the pulse-rate did not exceed 90 beats, and the minimum pressure did not exceed 100 mm. Hg.

TABLE 2.—TOTAL ENERGY INDEX IN ONE HUNDRED AND SIXTEEN NORMAL CASES

Maximum Pressure mm. Hg.	No of Cases	Average Total Energy, mm. Hg.
From 100 to 120	16	15,196
From 120 to 130	59	17,086
From 130 to 140	22	17,450
From 140 to 150	12	18,722
From 150 to 160	7	20,705

Judging by Table 2 and in the light of what is known to be the normal maximum, the normal minimum pressure and the pulse-rate, it appears that the highest energy index in the normal person is close to 20,000 mm. Hg per minute.

For the sake of simplicity, I believe that it does not involve too great an error to strike off the last two figures of our totals and to say that in a given case the energy index is 151 or 170, as the first two total energy indexes in the series would show. Or we may designate the degree of hypernormal expenditure by the percentage of increase over 20,000. Thus a case with a total energy index of 30,000 may be designated as showing a 50 per cent. increase, and so on.

I have picked out of my records of the past year ten cases of advanced cardiovascular and renal involvement. These patients were all seriously ill, and recognized as such from the start. Up to the present time five of them have had apoplectic strokes. Cases 4, 8, 9 and 10, which are the younger patients of the series, each show an extraordinary amount of total energy expenditure per minute, and judging by their present symptoms, it seems only a matter of a comparatively short time until either the heart or a blood-vessel will give way, although we do occasionally see patients with very high pressure maintaining their health for long periods.

TABLE 3.—THE TOTAL ENERGY INDEX IN HYPERTENSION

Case No.	Age	Max.	Min.	Pulse-Rate	Total Energy	Remarks
1	66	182	100	74	20,868	Six months later, cerebral hemorrhage.
2	63	164	100	90	23,760	Eight months later, cerebral hemorrhage.
3	69	192	176	66	24.288	Six months later, cerebral hemorrhage.
4	50	235	120	84	29,820	Symptoms of threatened cerebral hemorrhage.
5	51	235	120	84	29,820	Six months later, cardiac failure.
6	59	220	140	84	30,240	One month later, cerebral hemorrhage.
7	54	200	140	108	36,720	One month later, cerebral hemorrhage.
8	52	220	160	96	36,480	Symptoms of cerebral angiospasm
9	35	180	145	120	39,000	Chronic nephritis; albuminuric retinitis.
10	56	280	140	120	50,400	Serious symptoms of cerebral arteriosclerosis.

A review of the figures in Table 3 makes it at once apparent how important it is that we include the complete triad—the maximum pressure, the minimum pressure and the pulse-rate—in order that we may obtain a definite idea of the cardiovascular energy expended, and of the strain under which the heart and the blood-vessels are laboring.

THE PRACTICAL SIDE OF DERATIZATION WITH FLUE-GAS

WITH SPECIAL REFERENCE TO THE PORT OF PHILADELPHIA

M. E. BERKOWITZ,
Pharmacist, United States Public Health Service
PHILADELPHIA

Although many writers have discussed the problem of fumigating vessels by the use of sulphur or its dioxid, very little seems to be known or written about the use of flue-gas for the destruction of rats on vessels. Surgeon W. G. Stimpson and Passed Assistant Surgeon Norman Roberts of the Public Health Service have written on this subject regarding the composition of flue-gas and its efficiency and use. The present article will treat of its practical application.

When a vessel is inspected at quarantine and requires fumigation, a letter of instructions is given to the captain, and arrangements made through the local agents for her fumigation at the anchorage or dock as soon after her arrival as possible. A card is then filled out with the necessary data concerning the vessel and filed for future reference.

Coke is the agent employed for the production of the gas, and is burned in the furnace of the boilers of the quarantine vessel. It is spread evenly and to a depth of from 8 to 12 inches over the fire. A pipe leading from the side of the smoke-stack conveys the flue-gas to a tank in which the gas is cooled and washed. A blower operated by a turbine not only produces a forced draught and draws the gas into the washer, but also blows the gas through an upright pipe leading above the deck of the quarantine vessel, at which point connections are made with hose used to convey the gas to the vessel to be fumigated.

The personnel of the fumigating force consists, in addition to the crew of the quarantine vessel, of the officer in charge of the fumigation and two attendants. One of the attendants is assigned to the forward part of the vessel and the other to the aft, the engine-room being the dividing line. The attendants inspect the vessel and determine what connections are to be made, see that all compartments are properly prepared and act as watchmen to prevent accidents from the use of the gas.

Great care must be exercised in seeing that no one remains in the stoke-hold or engine-room during the fumigation. When the forecastle is being prepared, a careful search must be made in each bunk to make certain that no member of the crew is asleep, and all ports must be closed but not bolted. When there is a connection between the forepeak and forecastle, all hatches of the former compartment are opened, and this entire section is fumigated at one time. In the fumigation of compartments that have connecting doors, these are opened to allow the gas to be thoroughly diffused and make it possible to fumigate that particular section of the vessel without making more than one connection. All hatch-covers of holds must remain in place until after the fumigation. As the opening to the forecastle is usually not fitted with a door, a canvas cover must be provided.

The paraphernalia used in fumigation consists of canvas hose, metal pipes, a metal cone, a canvas apron with a hole of suitable size in the middle for inserting the hose, and a lantern, The cone is intended for use at port-holes that are either of smaller or larger diameter than the hose. The metal pipe is usually used when it is desirable to make a single connection between the side of a ship and hold. When openings are not fitted with suitable covers the apron is used.

The process of fumigation is as follows: After all connections have been made the blower is started, drawing approximately 1,500 cubic feet of gas from the furnace and forcing it into the compartment to be fumigated. An opening is provided at a point as nearly as possible opposite that at which the gas is being introduced, for the escape of air forced out by the gas. The lighted lantern is then lowered into the compartment to ascertain whether the gas is being properly diffused, the gas extinguishing the light when of sufficient strength on reaching the level of the lantern.

After the lantern is extinguished all openings are closed and the blowing continued for from five to ten minutes; the compartment is kept closed for from one-half to one hour, depending on the particular conditions. When compartments used for living-quarters are being fumigated, formaldehyd gas is introduced with the flue-gas to act as a warning to any one remaining therein.

Hatch-covers and ventilator-covers are removed after sufficient time has elapsed, the ventilators turned to the wind, and all doors, ports and other openings of living-quarters are opened. To determine whether or not a compartment is safe and free from gas the lighted lantern is again used, being lowered into the compartments or placed near the doors, and no one allowed to enter while the light is extinguished. When the light remains burning brightly for a short time, the compartment is considered safe for occupancy or ready for unloading. When little or no ventilation is provided in a compartment, the blowing of the gas is continued for a longer period than usual, and then fresh air blown in, which causes sufficient diffusion to expel all the gas.

While the vessel is being fumigated, the officer in charge of the fumigation inspects the life-boats for rats or rat signs. If any are found the chief officer is instructed to have metal covers made to fit the davit-lines similar to those used around the anchor-chains, and to have all holes in the covers repaired.

After the fumigation is completed, the captain or chief officer is given a blank form on which he is requested to note the number of dead rats found after his vessel has been cleaned, and return the form to the local quarantine office, he is also instructed to have all dead rats burned, unless collected for examination. The officer in charge of the fumigation completes a form relative to the fumigation which is filed at the office for the information of the medical officer in charge of the station, and as a record in the event of an accident occurring during the fumigation.

At the close of each week a report of the vessels fumigated, their port of departure, cargo, method of fumigation and the number of dead rats reported, is forwarded to the bureau, and the cards are then filed in an alphabetical order.

NOTES

The equipment for a vessel engaged in fumigating with flue-gas should include a pulmotor and an oxygen helmet; also an Orsat apparatus for testing the carbon monoxid content of the gas. The use of live rats, from time to time, as a control in the work is also greatly recommended.

The length of time necessary to complete a vessel depends on size, construction, means of ventilation and time necessary to make and change connections. The average is about three hours for a loaded freight-vessel, and about two hours for the usual size fruit-boat when unloaded.

If it is intended to begin unloading immediately after the fumigation, attention is first given to the holds. The gas will penetrate easily and kill all rats in a compartment, and as it is unlikely that a rat will come on deck during the day, it is safe to finish one part of a vessel and allow it to be opened for the escape of the gas while another is fumigated. When two connecting holds are separated by a wooden bulkhead, it is better to do each compartment separately, rather than allow the gas to diffuse through the bulkhead. If there are small compartments in a vessel not connected with one which is being fumigated, a careful search is made, and if there is no possibility of a rat being harbored therein, this compartment may be exempted from fumigation.

NOTE: Since the preceding article was written the quarantine steamer *Neptune* has been equipped with a Schutte and Koerting type of the Harker fumigating apparatus capable of delivering three thousand cubic feet of flue gas per minute, which reduces considerably the time required for fumigating a vessel. Vessels requiring fumigation are now treated at quarantine before being allowed to dock.

BASIC FUCHSIN IN SURGERY

ITS WIDE RANGE OF USEFULNESS

W. H. DONNELLY, M.D.
BROOKLYN

In the work of treating the employees of a rapid-transit system employing almost 15,000 men, perhaps the commonest chronic condition we have to deal with, and also one of the most unsatisfactory, is ulcer of the leg.

It is so common among surface-car motormen that it has come to be known as "motorman's leg."

In considering the etiology of this condition, after excluding constitutional conditions and trauma, one is struck by the fact that motormen are very prone to it, while the conductors are comparatively free.

Of course the explanation is simple. The average motorman is obliged to stand in one spot for hours at a time, and the only rest he obtains is by transferring his weight from one foot to the other from time to time. Thus he does not have the stimulation to venous return of circulation in the leg caused by muscular action—which is obtained by the comparatively small amount of walking done by his mate, the conductor.

The average motorman who has been in the service for five years or more is liable to be found to have one or more of the following conditions, in their order of frequency: (1) varicose veins, (2) ulcer of leg, (3) flat-foot, (4) hemorrhoids, (5) varicocele. These all are due to the same cause, prolonged standing with no walking. The rarity of these conditions in conductors is remarkable. Therefore, having run the gamut of treatments and dressings for chronic leg-ulcer without having found any one application uniformly successful, I was deeply interested in the article by May and Heidingsfeld[1] on the use of basic fuchsin in that condition. I had remarked that almost every application used by me in these cases of ulcer had tended to irritate the surrounding skin and produce a dermatitis. The statements of May and Heidingsfeld that fuchsin preparations (*a*) were absolutely non-irritant, (*b*) were proved to be non-toxic, (*c*) did not coagulate albumin, and (*d*) encouraged epithelial and granulation growth, at once influenced me to follow their suggestions.

I noted that the cases described were hospital cases and therefore probably in patients confined to bed. None of the patients whose cases I deal with in this article were confined either to bed or to the house, and most of them were doing their usual work on the cars. This was a much more severe test of the fuchsin treatment. I heeded the warning given in the article against the use of commercial fuchsin, and insisted on obtaining Grübler's Fuchsin für Bakterien. The formula used was:

Fuchsin	1
Petrolatum	5
Lanolin q. s. ad	100

This makes a fine smooth paste which does not melt and run away or soak through the dressing. From the first application, not only have I seen no irritant effect, but on the contrary the action of the dye seems to be a remarkably sedative one.

Of thirty cases of leg-ulcer between June 1 and December 15, only one has failed to respond, and in this case repeated trauma, and an alcoholic habituation must be taken into consideration. Having obtained such uniformly gratifying results in these chronic leg-ulcers I was prompted to extend its use to burns, abrasions denuded matrices of evulsed nails, ingrowing toe-nai operations, granulating wounds following suppuration and incision — in short, to all conditions in which there was ulceration or loss of epithelial covering. In burns the results have been little short of marvelous, especially in electric burns, which are notoriously hard to heal Not only does its use in second- and third-degree burns prevent suppuration and encourage epithelial growth but the soothing effect of its application is very gratifying to the patient.

I have compiled a short synopsis of the number of cases of each condition treated between June 1 and Dec. 15, 1913:

Varicose ulcer of leg	30
Burns	17
Evulsed nail	15
Granulating wounds, mostly infected, base of carbuncle, etc.	14
Ingrowing toe-nail operations	10
Sloughing of sutured wounds	6
Total	02

The results have been invariably good with the one exception mentioned above.

The only objection to the treatment is the bright red color of the dye, and the difficulty of removing its stain from the hands and clothing. This is a minor matter however, as alcohol will effectually remove the stain from the skin even after many days, and the clothing can be protected by a little care in applying the dressing and bandages.

My only reason for not using it as a moist dressing for wounds, as May did, is that I have been obtaining exceedingly satisfactory results from the use of tincture of iodin and dry dressings.

I wish to urge the extensive use of fuchsin not only in chronic ulcers but also in burns, abrasions and in all cases in which epithelial covering is wanting. It seems to fill a long-felt want in such cases.

1019 Beverly Road.

SIGNIFICANCE OF ELEVATED BLOOD-PRESSURE IN PREGNANCY

FRANCIS ASHLEY FAUGHT, M.D.
PHILADELPHIA

The wide-spread interest in the sphygmomanometer, and its almost universal employment, have developed a wealth of clinical data bearing on the blood-pressure in a large variety of conditions. On the whole, this information is enlightening, and in many instances materially assists in the solution of clinical problems. Among the specialists, the obstetrician has learned to place great dependence on the guiding finger of the sphygmomanometer. Possibly by accepting too literally the conclusions of the pioneer writers, that continued high pressure calls for surgical interference, he may be led into error through lack of careful study and observation, and a failure to estimate the true value of the blood-pressure findings.

The one point which does not seem to have been clearly brought out is the relative danger of the high pressure of varying origin which may occur during pregnancy. Just as there are many persons who for a long time have moderate degrees of chronic kidney involvement, associated with little or no discomfort and few definite signs of serious disease in spite of the high pressure maintained, so also one may find women, who, during the course of their pregnancy, show a sustained high pressure with transitory or absent concomitant phenomena, and at no time present the picture of even a mild toxemic state. These most certainly, should be separated from the pregnant cases showing even a moderately elevated blood-pressure accompanied by some or all of the familiar signs of the toxemia of pregnancy.

While the first group may need special watching and careful management, they should by no means be looked on as subjects for surgical interference. This fact emphasizes the great importance of careful general clinical observation in addition to blood-pressure studies. In this connection the urine will often, but not always, serve as a valuable guide. (The value of urinalysis in doubtful cases is greatly increased when the total twenty-four-hour excretion is collected for examination.)

In the toxemia cases, the gradually rising pressure, the persistent nausea, the head pains and the characteristic urinary findings (diminished quantity with increasing amounts of albumin, casts and blood-cells), all point to an acute and progressive condition.

When it comes to a decision we may be further aided, if we can obtain evidence through the history of a previously existing kidney involvement sufficient to account for the fairly well-sustained high blood-pressure found on successive observations. Moderately elevated pressure may persist throughout a pregnancy while the urine continues to be large in volume, of low specific gravity, without albumin entirely, or with only minute quantities and often an entire absence of formed pathologic elements.

The following abstracts taken from case records are examples of the two types of high pressure above referred to.

Case 1.—Mrs. W. T., aged 37, undecimpara, was first seen Sept. 17, 1913. The last period was early in June. In the latter part of July moderate nausea and vomiting occurred, but no edema or other special symptoms referable to her condition. The bowels were constipated but were opened daily by enemas. The pulse was 88, and the blood-pressure 180 mm. Hg. At this time the patient was given a pill for constipation and directions in regard to diet, personal hygiene and habits, etc.

September 22, patient was much relieved of gastric disturbances. Pulse was 100 and blood-pressure 170 mm. Hg.

September 6, pulse was 100 and blood-pressure 170.

September 30, pulse was 90 and blood-pressure 160. Careful questioning developed the fact that following a plastic operation several years ago, unconsciousness lasted several days with total anuria, which was followed by evident signs of an active kidney lesion, for which she had been treated.

The urine on two occasions (in September, 1913) showed specific gravity from 1.010 to 1.018 with a trace of albumin, no casts, blood-cells or pus, but an occasional cylindroid and a few shreds of mucus. Subsequent observations warrant the assumption that the high pressure occurring in this case is due to an old kidney lesion and is not the result of a toxemic state and therefore does not demand evacuation of the uterus.

Case 2.—Mrs. C. B., aged 22, primipara (time calculated to March 30, 1912), represents a fair type of a moderate degree of a toxemia of pregnancy. The patient was first seen Feb. 5, 1912, when she complained of very edematous ankles, nausea and vomiting, dizziness and headaches. Examination showed blood-pressure to be 180, with a large amount of albumin in urine. Three weeks' active treatment, including rest, sweat-baths and other eliminative measures failed to better the condition. During this time the pressure ranged from between 170 and 185, dropping once to 150.

March 7, over 50 per cent. of albumin was shown by Esbach; other conditions were about the same.

Labor was induced March 9, and delivery occurred the following day, after which the blood-pressure promptly fell to 125 mm. Hg. On April 3, the blood-pressure was 120 and there was no albumin in the urine.

Patient presented herself again on Oct. 14, 1912, when she was six weeks pregnant. At this time she showed some edema of the ankles, but had no other complaints. Examination of urine showed low specific gravity, but no albumin or other pathologic elements. This patient was carefully watched till the time of her delivery, June 3, 1913. Throughout this pregnancy the blood-pressure ranged between 110 and 125, the average pressure being about 120; the urine at no time contained more than a trace of albumin and never showed any other abnormal characteristics. Delivery and subsequent history up to the present time are entirely uneventful.

It is interesting to note in this case that the toxemia which occurred during the latter part of the first pregnancy did not occur in the second, and that the little time elapsing between the two pregnancies did not permit of much recuperation. Yet in spite of this, it is plainly evident that there did not result any permanent kidney damage, which is shown by the fact that in the second gestation the blood-pressure and the urinary and other findings remained normal.

EXPERIENCES WITH NOGUCHI'S LUETIN TEST FOR SYPHILIS

H. L. McNEIL, M.D.
HOUSTON, TEX.

For the past eight months I have been using luetin, as prepared by Noguchi, in selected cases in the Southern Pacific Hospital of Houston. I have been struck with its value in this class of cases, and in this kind of work, in which it is necessary to test numbers of men, and to do it with more or less rapidity.

The specificity of the test has impressed me as being decidedly valuable in the late cases of syphilis.

The technic has been carried out as recommended by Noguchi: 0. 07 c.c. of a mixture of equal parts of luetin and sterile normal salt solution, injected intradermically.

I have noted several anomalous reactions, which I shall describe briefly before taking up the series in more detail.

I have noted one of the so-called delayed reactions; that is, the site of injection appeared quite normal after forty-eight hours, and remained so for ten days, when there appeared a marked pustular reaction (Case 19). In one case a typical severe reaction appeared thirty-six hours after the injection, being typical, however, in every respect, and ran a regular course. This was a case, also, in which the Wassermann reaction was negative at the time; the patient had had a thorough treatment for syphilis, which had been contracted two and one-half years previously (Case 12).

I have noted two negative reactions in cases which were clinically tertiary lues. One patient was suffering from luetic iritis, and from a periostitis. He had a definite history of syphilis, incurred eighteen months previously, with practically no subsequent treatment.

The first test remained quite negative for twelve days. On the sixth day after luetin was given, vigorous antisyphilitic treatment was instituted (mercury inunctions to physiologic limit plus large doses of potassium iodid), with immediate improvement of all symptoms. On the twelfth day, a second injection of luetin was given, followed in forty-eight hours by a typical papular eruption, which later became pustular. Almost coincidentally with this reaction (twelve hours later), there occurred a similar reaction of about the same degree of severity at the site of the old injection, which had been made twelve days previously (Case 1). The other negative case was that of a man whose palate, soft and hard, was eroded, and who had an old urethrorectal fistula. There was a definite history of lues, practically untreated. The luetin reaction was negative. A second test, tried ten days later, was positive, not becoming pustular, however. The patient had been placed on antisyphilitic treatment on admission to the hospital, and was taking large doses of mercury and potassium iodid during the period elapsing between these tests (Case 3).

There were three positive reactions in patients who showed no definite clinical symptoms of syphilis, and who gave no history. Two of these were negroes who had been injured in accidents. Both gave a definite positive reaction. The other was a Mexican with chronic arthritis. All three denied lues, but owing to the races, and the social status of the patients, the negative history is to be doubted. The other twenty-two control cases, including typhoid, pneumonia, acute articular rheumatism, influenza, nephritis, malaria and endocarditis, were negative except one case of aortic and mitral insufficiency, with extensive arteriosclerosis, which showed a definite pustular reaction (Case 45), and one case of mitral regurgitation, and probably dilatation of the aorta, which showed a positive pustular reaction (Case 46). The last two were both elderly white laborers who were low in the social scale; both improved considerably under specific treatment, and should probably be considered as syphilitics, clinically, even without laboratory assistance.

There were no severe constitutional reactions from any of the tests, although a few patients complained of feeling ill, with slight headache and loss of appetite for about twenty-four hours.

In interpreting the following reactions, I have considered as positive only those which were definitely positive, that is, in which there was at least a distinct, indurated, red, papule, persisting for at least four days after the injection. All doubtful reactions were considered negative. Most of the reactions were pustular. In the following reports, papular reactions are denoted by + and pustular reactions by + +. Negative reactions are denoted by —.

REPORTS OF CASES

Case 1.—H. Iritis, periostitis, gumma of liver, history of chancre, followed by secondaries, eighteen months previously; practically no treatment. Luetin —.

Case 2.—H. (Same patient as Case 1) twelve days later; immensely improved after forcing mercury and potassium iodid. Luetin + +.

Case 3.—Eroded palate, urethrorectal fistula, history of syphilis ten years ago. Luetin —.

Case 4.—Same patient as Case 3, ten days later. Luetin +.

Case 5.—Castro, Mexican, otitis media chronica. Wassermann positive. Luetin +.

Case 6.—P. Cerebral lues. History of syphilis. Luetin +.

Case 7.—M. General paresis. Luetin + +.

Case 8.—S. Chancre, followed by secondaries three years ago. Thorough treatment (several courses of mercury [thorough], followed by two treatments with salvarsan). Healthy wife and baby. Wassermann negative several times. Luetin —.

Case 9.—B. Syphilis, primary and secondary, four years ago, followed by mercury for two years. Healthy wife and baby. Wassermann negative several times. Never had salvarsan. Luetin + +.

Case 10.—D. Syphilis, primary and secondary, two years ago. Thorough treatment with mercury. Salvarsan three times. Wassermann negative. Luetin —.

Case 11.—S. Syphilis, primary and secondary one year ago. Salvarsan twice. Mercury constantly. Wassermann negative. Luetin + +.

Case 12.—B. Syphilis, primary and secondary, two and a half years ago. Salvarsan twice. Two courses of mercury of several months' duration each. Wassermann negative. Luetin + +.

Case 13.—S. General paresis. History of syphilis twenty years ago. Luetin +.

Case 14.—J. Syphilis, primary and secondary, one year ago. Salvarsan once. No mercury. Suffering from periostitis. Luetin + +.

Case 15.—C. Sciatica. History of syphilis four years ago. Patient took mercury for few months only. Luetin +.

Case 16.—L. Argyll Robertson pupil, absent knee-jerks, mental aberration, no history of syphilis, Wassermann negative. Luetin +.

Case 17.—F. Syphilis, secondaries. Wassermann positive. Luetin —.

Case 18.—A. Syphilis secondaries. Luetin —.

Case 19.—H. Chancre hard. Luetin —.

Case 20.—P. Syphilis twenty years ago, followed by thorough treatment with mercury; patient has taken mercury off and on for past twenty years. Salvarsan twice. Wassermann negative. Luetin —.

Case 21.—H. Alopecia, loss of eyebrows. No history of syphilis. Wassermann positive before treatment. Salvarsan twice. Thorough course of mercury for two months. Luetin —.

Case 22.—S. Syphilis eight months ago, primary and secondary. Salvarsan once, mercury constantly. Luetin + +.

CONTROL TESTS

Case 23.—W., negro. Injury to foot, amputation of toe. Luetin —.

Case 24.—R., Mexican. Pulmonary tuberculosis. Luetin —.

Case 25.—B. Pleurisy, myocarditis. Luetin.—.

Case 26.—M. Typhoid. Luetin —.

Case 27.—T. Acute gastritis. Luetin —.

Case 28.—M., negro. Nephritis. Luetin —.

Case 29.—H., negro, aged 30. Injury to back. Patient denies lues. Wife had miscarriage at seven months. Luetin +.

Case 30.—M., Mexican. Amputation of foot. Luetin —.

Case 31.—W. Bronchitis. Luetin —.

Case 32.—R., negro, aged 40. Fracture of arm. Patient denies lues. Scars of old ulcers on shins. General enlargement of lymph-nodes. Luetin +.

Case 33.—C., Mexican. Carcinoma ventriculi. Luetin—.

Case 34.—I. Influenza. Luetin —.

Case 35.—Mexican laborer, aged 28. Chronic multiple arthritis. Patient denies lues. Luetin +.

Case 36.—L. Mitral stenosis. Luetin —.

Case 37.—Mexican. Malaria. Luetin —.

Case 38.—P., Mexican. Typhoid. Luetin —.

Case 39.—H. Acute gonorrhea. Luetin —.

Case 40.—S., Mexican. Amputation following accident. Luetin —.

Case 41.—Negro. Gonorrheal rheumatism (acute). Luetin —.

Case 42.—E., negro. Pneumonia. Luetin—.

Case 43.—C. Acute articular rheumatism. Luetin—.

Case 44.—Nephritis. Luetin—.

Case 45.—Mc., aged 48. Mitral insufficiency, dilatation of aorta. Denies lues. Luetin + +.

Case 46.—W., white, laborer, aged 54. Mitral and aortic regurgitation, arteriosclerosis (generalized). Patient denies lues. Luetin + +.

Case 47.—S., negro. Sprained back. Luetin —.

Case 48.—S. Unexplained attacks of periodic vomiting. Luetin —.

CONCLUSION

My feeling, after this limited experience, is that this is distinctly a valuable test, and that when it is positive we are dealing with syphilis. It has been of service to me in several cases in which syphilis would probably not otherwise have been suspected, and in which it was confirmed by either the Wassermann reaction or by the therapeutic test.

I wish to thank Dr. Noguchi of the Rockefeller Institute for his kindness in furnishing the luetin which was used in these tests, and Dr. R. W. Knox, chief surgeon of the Southern Pacific Lines, for permission to carry out and publish this work. I also wish to thank Dr. H. C. Moore of Houston for furnishing me with a few very interesting cases from among his own patients.

2612 Smith Street.

HEMORRHAGIC HYPERNEPHRITIS

WITH REPORT OF CASE

JOSEPH O. WALKUP
First Lieutenant, Medical Corps, United States Army
FORT BAYARD, N. MEX.

No excuse is offered for this case-report other than that it is an unusually distinct picture and an uncommon condition. Munson, quoting Arnaud, states that adrenal hemorrhage is found in 1 per cent. of cases. I agree with Munson that this figure is high. In 652 necropsies performed in the United States Army General Hospital for Tuberculosis, with examinations of all organs, but one case has been recorded. The subject is not so well treated in medical literature as other conditions equally uncommon. A majority of the text-books do not speak of the condition and many only mention it. Very few so treat the subject that one could reasonably be expected to recognize it clinically.

The etiology is unknown. Microscopically, fatty degeneration is marked (Adami). In my experience, typical fatty degeneration in the adrenal with atrophy of the cell nuclei is very uncommon, especially in the cortical portion. Fatty infiltration is apparently not so rare. I have noticed that when fatty degeneration or infiltration is present in the adrenal, the fibrous tissue of the pancreas is usually increased and the islands of Langerhans are apparently enlarged. Whether this is a coincident or an etiologic relationship I am not prepared to state. Infection, trauma, thrombosis, etc., have been advanced as etiologic factors. None of them, however, are thoroughly satisfactory.

The symptoms are not well defined as a rule. Rolleston gives the most characteristic symptoms as "sudden onset with fever, violent pain in the hypochondrium radiating to the loins, convulsions, vomiting, diarrhea, and later tympanites, collapse and death within forty-eight hours from the onset." Karakascheff emphasizes asthenia and intestinal irritation (Doch). The following case may assist in defining the symptom complex:

History.—C. L. R., white, man, aged 43, sergeant, who had served in the army seventeen and one-half years, entered the hospital Nov. 22, 1911. The family history was negative. The patient had had dysentery in 1909, and malaria in 1908. In July, 1898, the left ear began, without pain, to discharge pus, and had discharged off and on ever since. Patient had had growths in both sides of scrotum ever since he could remember. The present illness began in April, 1909. Patient was hoarse, had slight expectoration and cough. In April, 1911, he contracted a heavy cold, and the hoarseness, expectoration and cough became worse. He had gradually lost 50 pounds since April, 1909. His best weight was 220 pounds, in 1896. Sputum was positive for tubercle bacilli in October, 1911.

Examination.—On admission the patient's temperature was 98.8, pulse 84, weight 149 pounds, cough and expectoration moderate. Expectoration was mucopurulent. There were numerous tubercle bacilli; digestion was unimpaired. Blood and urine were normal. The patient was deaf in the left ear. There was a large perforation in the posterior inferior quadrant. Examination of larynx showed infiltration and ulceration of posterior commissure. Lungs showed signs of healed tuberculous infiltration in the upper part of both superior lobes. There was a slightly active tuberculous infiltration at the summit of both inferior lobes. The abdomen was normal. Both testicles were malformed—lobulated. There was a right inguinal, indirect, incomplete, reducible hernia, which had developed gradually during the past two years as a result of coughing.

Treatment and Course.—Under routine treatment the patient became free from clinical tuberculous activity in March, 1912. Tubercle bacilli were present in sputum. The weight was 160 pounds. Patient's condition remained the same until discharged on surgeon's certificate of disability in October, 1912. Tubercle bacilli were present in sputum. The weight was 176 pounds. The general condition was favorable. The result was noted as improvement.

Second Admission.—After leaving Fort Bayard the patient went to Pennsylvania where he remained for seven months, doing no work. Appetite and digestion became impaired, resulting in the loss of 31 pounds in weight. Cough and expectoration increased. On readmission, May 14, 1913, temperature was 98.2, pulse 96, weight 145 pounds. Patient complained of anorexia and of griping pains in lower abdomen, especially after breakfast; had had a diarrhea the past two months. An active tuberculous infiltration was found in the greater part of both superior lobes and at the summits of both inferior lobes. There was a cavity at the right apex posteriorly. This condition of the lungs was complicated by tuberculous otitis media, left; tuberculous laryngitis, and tuberculous enterocolitis. Blood and urine were normal.

June 14, 1913: General condition of patient was unimproved. He was much weaker and had lost 10 pounds in weight. Temperature was from 99 to 100. Patient continued to have griping pain and constant diarrhea. Lungs showed fewer râles.

July 14: General condition was unchanged from last report. Diarrhea continued from four to five movements daily. Diagnosis and complications remained unchanged.

August 15: This morning patient developed an attack of sudden pain in the upper right abdomen localizing at the angle of the right costal arch. Pain radiated to angle of right scapula and to point of right shoulder. Abdominal muscles were rigid. Temperature, morning, was 98.8; evening, 100. Pulse was 96, full and hard. Diarrhea was uncontrolled. Urine was normal. Nothing pathologic was found in fecal analysis.

August 19: Patient was apparently improving. Abdominal pain was becoming less though still there was a painful point at angle of right costal arch. Pressure caused pain to radiate to point of right shoulder and to angle of right scapula. Morning temperature was 98; evening temperature, 99.2; pulse 84, high tension.

August 20: Just after breakfast patient suffered an attack of acute pain in the upper left abdomen localizing at angle of left costal arch, but radiating to point of left shoulder and angle of left scapula on pressure. Pain was not so severe as on the 15th. Morning temperature was 98; evening temperature, 99.6; pulse 96, high tension. There was occasional vomiting of watery fluid containing bile. Diarrhea was increased.

August 21: The condition was apparently unchanged from that of the 20th. Morning temperature was 97.6; evening temperature, 99.8.

August 22: While the nurse was out of the ward the patient arose and went to the water-closet about 20 feet away, fainted and fell to the floor. The nurse stated that the patient was entirely unconscious, but had a very hard pulse; breathing was shallow. The patient was put into bed and given 15 c.c. of whisky, after which he revived and complained of severe abdominal pains radiating to his shoulders. The medical officer was summoned, but the patient developed a severe convulsion and died at 8:55 a. m., about twenty minutes after fainting and before the medical officer arrived.

The clinical diagnosis was chronic pulmonary tuberculosis and tuberculous enterocolitis. Hemorrhage or perforation of duodenal ulcer was suspected as the cause of death.

Necropsy.—This was held at 1:30 p. m., Aug. 22, 1913. The body was that of a dark, emaciated white man, aged 45. Abdominal walls were retracted and rigid. Rigor mortis was absent from the extremities and neck; body heat was present.

Tuberculous infiltrations were found in the upper parts of all the lobes of the right lung and of the entire left lung.

The heart and pericardium were apparently normal.

No definite pathologic condition other than passive congestion could be demonstrated in the liver macroscopically.

Evidence of beginning intestitial nephritis was found in the kidneys.

The spleen showed passive congestion.

The pancreas was slightly fibrous.

Adrenals: The right adrenal is enlarged and situated in a blood-clot about the size of a hen's egg. The clot appears to be composed of two parts: an older portion which is almost black and a younger portion which is bright red and apparently of recent origin. The surface of the gland and the hematoma are free from evidence of tubercles. In some parts of the cut surface of the gland it appears as though there had been hemorrhage within the gland substance. No definite macroscopic change can be demonstrated within the gland.

The left adrenal is within a blood-clot as large as a fist. The greater portion of the clot is above the gland, while in the right the gland is almost within the center of the clot. The clot about the left gland does not appear to be made up of two portions, a younger and an older, as is the clot about the right. This hematoma on the left side is apparently very recent in origin. The clot is sufficiently large to incorporate the semilunar ganglia; the ganglion, however, cannot be definitely identified. The margin of the hemorrhage extends to the celiac axis. The sectioned mass shows the gland to be apparently free from disease or hemorrhage.

Intestines: The small intestines and stomach are apparently free from pathologic change other than a slight reddening and thickening of the mucosa of the stomach and duodenum. The large intestines contain several large tuberculous ulcers. The ulcers have bright red, indurated, raised edges. A few tubercles are discernible in the bottom of the ulcers.

Microscopic Findings: Adrenals: The left adrenal shows a diffused and general fatty degeneration. Within and about the glands are numerous evidences of hemorrhage. There are more evidences of hemorrhage externally than internally. Very few cells can be recognized as gland-cells. The degeneration has apparently been very rapid and of equal extent throughout the organ. The same condition as in the gland proper is present in the small clumps of adrenal tissue seen about the periphery of the glands. The medullary and cortical portions are equally involved. The degeneration however, is more advanced in the medullary portion, judging from the fact that the few remaining cortical cells stain more distinctly than those of the medullary portion. There is no evidence of tubercles in the adrenals. The right adrenal shows the same pathologic condition as the left. The hemorrhage is more distinct within this gland than within the left.

Pancreas: The interstitial tissue is increased. The islands of Langerhans are unusually large. The blood-vessel walls are thickened, as are the walls of the ducts.

Pathologic Diagnosis: The cause of death was hemorrhagic hypernephritis. Associate causes of death were fatty degeneration of adrenals, and chronic pulmonary tuberculosis.

Munson states that a positive clinical diagnosis can be made only when the glands are sufficiently enlarged to be recognized by palpation. While this is to be borne in mind, the majority of patients will be so exquisitely tender that palpation cannot be performed thoroughly enough to demonstrate enlarged glands. Theoretically, the blood-pressure should be very low — at least shortly after the hemorrhage. It is possible that the pressure might be raised immediately after the hemorrhage, as the absorptive surface would be suddenly increased. This should not last long, as the gland would certainly be traumatized so as to reduce its secretion, and pressure would fall through the lack of normal secretion.

Apparently the cardinal symptoms are profuse watery diarrhea, pain localizing at angle of costal arch and radiating, especially on pressure, to the shoulders and loins, and symptoms of collapse with a high blood-pressure.

From a theoretical point of view the treatment should be absolute rest, light diet and adrenal extract. Diffusible stimulants which dilate the vascular system are to be avoided.

In conclusion, I will state that Sergeant R.'s diarrhea may have been due to tuberculosis; but one who has attended necropsies on tuberculous subjects for any length of time always wonders why diarrhea is not a constant symptom of tuberculous colitis, enteritis or enterocolitis. In less than 30 per cent. of our cases of tuberculous bowel disease coming to necropsy was there a history of diarrhea. There is apparently but little relationship between the diarrhea and the extent of a tuberculous condition present in the intestine. It may be that adrenal changes are a factor in tuberculous enteritis, colitis or enterocolitis.

DETECTION OF MERCURY IN THE EXCRETIONS *

KARL M. VOGEL, M.D.
AND
O. IVAN LEE, B.S.
NEW YORK

The identification of mercury in the urine, stomach-contents or feces of persons supposed to be suffering from poisoning by this metal is often a matter of great diagnostic importance, and is of especial significance owing to the fact that if the proper eliminative treatment is begun without delay the patients' lives can be saved in a considerable proportion of the cases. The newspaper notoriety given to recent cases of poisoning with mercuric chlorid, the ease with which the substance may be obtained, and the mistaken but prevalent idea that the death caused is rapid and without discomfort, have procured for this agent a wide vogue among those attempting suicide; while its popularity as a household antiseptic causes accidental poisonings to occur with considerable frequency. The history to be obtained from such patients or their friends, however, is often extremely unsatisfactory, and there is nearly always room for doubt whether or not the poison has actually been taken, and if so, whether the amount is large or small. Most of the cases of accidental poisoning occur at night through the victim's having swallowed something from a bottle in the dark, and often there is merely the suspicion that what was ingested came out of the poison container and not from its innocent neighbor, so that the patient and his friends remain in a state of mind which is uncomfortable, to say the least. Would-be suicides, on the other hand, frequently deny the nature of the substance taken, and the only proof possible may be that of demonstrating the poison in the stomach-washings or in the urine or stools. As a result the occasions in which it is necessary to test for the presence of mercury in the excretions are not so very rare, but unfortunately most of the methods available for this purpose are far too complicated to be suitable for clinical application. In two cases of mercuric chlorid poisoning, one with suicidal intent, the other accidental, recently treated at St. Luke's Hospital, and in a third from outside, the following procedure, which is a combination of various steps from several older methods, was found to be very satisfactory in identifying the poison and following its elimination in stomach-contents, urine and feces.

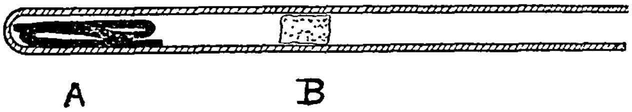
---

* From the Pathological Laboratory of St. Luke's Hospital, New York. Dr. F. C. Wood, Director.

In dealing with urine, about 150 c.c. is taken, and in order to break down the organic compound in which the mercury is likely to be present, it is acidulated with 5 c.c. of concentrated hydrochloric acid and evaporated over a free flame until its bulk has been reduced to 25 or 30 c.c. About 2 c.c. of hydrochloric acid is added to replace the loss by evaporation, and enough potassium chlorate to oxidize thoroughly the organic material present. This usually requires about 2 gm., and when it has been effected the fluid becomes pale yellow or colorless. It is then diluted to about 60 c.c. and is boiled vigorously until the chlorin gas previously evolved has been driven off, which is shown by the absence of chlorin odor from the steam. The solution usually darkens again on cooling. A piece of copper wire (about 18 gage) about 4 cm. in length, bent back on itself twice and cleansed by boiling a short time in a test-tube with dilute hydrochloric acid, is dropped into the solution and allowed to remain for an hour or more. If considerable amounts of mercury are present it will then be found to be coated with a silvery film of metallic mercury; but this is not sufficient to establish the identity of the metal, and if it exists only in traces the changes in the appearance of the wire may be inconclusive. The wire is accordingly removed from the dish with a glass rod, is washed with a little water and is gently dried by rolling it on a piece of filter-paper, pains being taken to avoid unnecessary handling and attrition. It is then allowed to slip to the bottom of a glass tube from 3 to 5 mm. in diameter and 15 cm. in length, which is sealed at one end, and is followed by a cylindrical plug of gold-leaf which is pushed into the tube until it is within 2 cm. of the wire. Such pellets of gold-leaf are used in filling teeth and are furnished by the dental supply-houses in the size required for the present purpose, so that when needed it is easy to obtain them from the nearest friendly dentist. The arrangement of the objects within the tube is shown in the accompanying sketch.

Holding the tube horizontally, the end containing the wire is gradually heated by brief successive introductions into the small flame of a Bunsen burner or spirit lamp, care being taken to avoid heating the part of the tube containing the gold-leaf. The latter must be examined frequently for any change of color, especially the end of the cylinder toward the wire. If mercury is present it will manifest itself by the appearance of a silvery patch of amalgam in this situation. If the amount of the metal is exceedingly minute there will be simply a pale discoloration of the gold, seen to better advantage with the hand-lens or by removing the pellet from the tube and examining it with the low power of the microscope; but if the amount is larger the deposit on the gold will be very easy to recognize.

If the pellet is too close to the wire the heat traveling along the tube may cause a deposit of mercury which at first was distinctly visible to become diffused so that it grows less evident. In doubtful cases the experiment should be repeated, using larger quantities of the material to be tested and allowing the wire to remain longer in the solution. If a positive result is obtained the tube may be sealed and kept as a permanent record. If further confirmation of the identity of the mercury is required, the gold-foil may be suspended in a tube containing a few crystals of iodin which are then very gently warmed. The mercury thus becomes converted into red mercuric iodid; or if the amount is considerable the metal may be distilled by heating the gold-foil in the tube and looking with the lens for a deposit of very minute droplets of metallic mercury in the cooler parts of the tube. Some idea of the amount of mercury present may be gained by weighing the gold before and after the formation of the amalgam.



Apparatus for the detection of mercury in the excretions; *A*, copper wire; *B*, pellet of gold-foil.

In testing stomach-contents or feces the same method is employed although the quantity of material taken is usually smaller. The material must be well mixed to insure getting a uniform sample of the specimen, especially in the case of stomach-contents if egg-albumin has been given as an antidote, as the mercury is then in the form of albuminate. The oxidation also takes longer, and larger quantities of potassium chlorate are required. Before the wire is placed in the solution, the latter should be filtered in order to remove any fatty substances, carbon or other insoluble materials.

Corrosive sublimate is readily reduced by organic matter to metallic mercury, and the latter, as well as mercuric chlorid, is volatile to a slight extent with steam, so that this must be kept in mind in evaporating or digesting solutions which may contain very minute amounts of the poison. The quantity of mercury which the copper is capable of abstracting from the fluid is a function not only of the concentration of the solution but also of the time of contact, so that if the test is negative after the wire has been immersed for one or two hours, another piece of wire should be dropped into the fluid and allowed to remain for a longer time, even over night.

In order to test the sensitiveness of the method the following experiments were done: A solution of mercuric chlorid was made containing 0.0001 gm. of mercury to the cubic centimeter, equaling 0.01 per cent.

or 1:10,000. Using this solution as a basis, successive dilutions showed that a definite positive reaction could be obtained when a solution containing 0.00002 gm. of mercury in the dilution of 1:1,000,000 was used, allowing the wire to remain in the solution three hours.

In order to make the controls more nearly resemble clinical conditions, experiments were made using three different specimens of albuminous urine, and two specimens each of stomach-contents and stools, to which definite amounts of the mercury solution were added, the mixture being allowed to stand over night before the tests were made. It was found that 1 mg. of mercury in 100 c.c., equaling a dilution of 1:100,000, could be detected in the urine, stomach-contents and stools, the wire being allowed to remain in the fluid two hours. In these cases the amount of amalgam formed on the gold was sufficiently large to be recognized with the unaided eye. Further control tests with materials to which no mercury was added gave negative results. The urine of twelve patients who had each received 2 grains of calomel the night before was also tested. In two of these a very faint positive reaction was obtained, showing the delicacy of the method, and also, that it is desirable before making a diagnosis of mercury poisoning to find out whether or not the patient has been given calomel.

The principle of securing deposition of the mercury on a metallic surface is made use of in many of the standard tests, such as the classical one of Reinsch and those described by Jolles,[1] Winternitz,[2] Almèn,[3] Brugnatelli,[4] Mergte,[5] Mauthner,[6] and Ludwig and Zillner.[7] All of these, however, involve complex manipulations or the use of reagents not always available, such as gilded platinum, powdered reduced copper, gold chlorid, etc. The formation of gold amalgam as a means of recognizing minute amounts of mercury also is not new, but it is believed that the technic suggested in the foregoing offers a simple, fairly rapid and exceedingly delicate method of testing for mercury which can easily be carried out by any physician.

680 Madison Avenue.

A CASE OF AMEBIC DYSENTERY OF THIRTEEN YEARS' DURATION CURED BY EMETIN HYDROCHLORID

G. W. McCaskey, A.M., M.D., Fort Wayne, Ind.
Professor of Medicine, Indiana University School of Medicine

The case about to be reported seems sufficiently important to be placed on record because (although this is only the second case that I have recognized) the fact has been recently acknowledged that the disease is not extremely rare in this latitude, and because of the important discovery of the specific amebicidal action of emetin hydrochlorid which was announced by Rogers[8] last year. There is no longer any doubt that, either *in vitro* or *in vivo*, it kills amebas with the same certainty that quinin kills the *Plasmodium malariae*, or salvarsan the *Treponema pallidum;* and that to the very short list of undoubted "specifics" capable of destroying certain micro-organisms within the human body without material injury to the host, emetin may now be added.

History.—The patient, a married woman, aged 70, consulted me Aug. 25, 1913, concerning constant and intractable diarrhea. The *family history* was uneventful. The patient had always been strong and healthy without illness of any consequence until thirteen years prior to the consultation, when the present trouble began. At that time, while in Tennessee, she had an attack of acute dysentery which, passing into a chronic diarrhea, has since been persistent. At times the discharge would be bloody and at others simply diarrheal. Throughout the thirteen years she had passed no formed stool.

During and following the acute illness she lost 30 pounds in weight but later regained much of it, and by extreme care in diet and extensive treatment had maintained a reasonable degree of health until some three or four years ago, when she again began to lose strength and weight. The heart was somewhat enlarged, the left border being 1 cm. to the outside of the midclavicular line. The blood-pressure was 140. The heart-sounds and rhythm were normal; there was no dyspnea, palpitation or edema.

The blood examination (which along with the other laboratory work was done by Dr. B. M. Edlavitch) showed hemoglobin 75 per cent., a leukocytosis of 17,600, polynuclears 61 per cent., small lymphocytes 20 per cent., large 10 per cent., transitional 1 per cent., eosinophils 7 per cent., basophils 1 per cent. Nothing was noteworthy in either physical examination or laboratory findings, beside the feces. These were semifluid, yellow, and contained mucus but no blood. Microscopic examination showed many amebas, which on the warm stage were found to be very actively motile. Meat-fibers and fats in the form of soaps and needle-shaped crystals were found in excess, probably due to the rapid transit of food debris through the bowel.

The patient entered Hope Hospital Sept. 8, 1913, for treatment. On that day Dr. M. F. Porter, Jr., who studied the case with me, gave her two-thirds grain of emetin hypodermically. Very mild nausea followed. September 9 she was given 1 grain. This was followed by increased nausea and very definite abdominal distress, which was unusual in her case. September 10 she was given 1 grain. Our stock of emetin then became exhausted and three days elapsed before the next injection was given. September 11 amebas were still present, but in greatly diminished numbers and nonmotile. Fifty-six hours after the third injection nausea increased in activity rather rapidly, several attacks of vomiting occurred and the patient was unable to take any solid food. Buttermilk was vomited shortly after it was taken. The abdominal distress which had continued was more severe at this time than earlier in the disease. September 13 no amebas were found, and 1 grain of emetin was administered, which was followed by distressing nausea and a largely increased number of liquid stools. A dozen stools were passed in the course of twenty-four hours. Nausea was still defined, abdominal distress troublesome and the patient suffering and greatly discouraged, except for the assurance that the cause of the chronic diarrhea had disappeared. No more emetin was given.

September 16 the patient had only three stools in twenty-four hours and of these the last was formed. The patient was very positive that this was the first formed stool which had passed in thirteen years, the stools having been constantly thin and watery during this time. The nausea and abdominal distress having disappeared, the patient was dismissed from the hospital. September 18 she was feeling perfectly well, except that normal appetite had not returned and solid food was repugnant to her. At this time the patient's condition was practically normal, about one formed stool daily being passed, and she was dismissed as presumably cured.

September 23, five days after dismissal, the patient returned with a recurrence of the diarrhea—six or eight loose, watery stools daily. Examination of the stools showed the presence of actively motile amebas. The cure had been only apparent, a sufficient number of the protozoa remaining to permit a complete recrudescence of the disease. She was not materially better than before the treatment.

[8] Rogers: Brit. Med. Jour., June 22, 1912.

The patient returned September 30 to resume treatment. She had considerable diarrhea and the stools contained amebas, although not so many as when treatment was first begun. On that date she was given two-thirds grain of emetin hydrochlorid hypodermically. October 1 and 2, she was given two-thirds grain; October 4 and 5, 1 grain. The injections were then omitted on the 6th and 7th. October 8, no amebas were found, but 1 grain of emetin was given. The patient returned October 13, having taken, according to directions, a saline laxative, as the amebas can be more certainly found in stools produced in this way. The stool contained no mucus and no amebas. On that day she was given an injection of 1⅓ grains emetin hydrochlorid. The patient was not seen again until October 17, when one or two formed, yellowish-brown stools, which contained no mucus and no amebas, were being passed daily. On this date an injection of 1 grain of emetin hydrochlorid was given. She visited the office again October 22 and 27, when the stools were examined and found to be perfectly normal in color and consistency and containing neither mucus nor amebas. The patient considered herself entirely well and was again dismissed as cured.

It is unnecessary to dwell on the fact that amebic dysentery is not so extremely rare in this latitude and should be constantly sought for even among patients who have not been south of the Ohio River. About a year and a half ago (April, 1912) a patient came under my observation (referred by Dr. Hackedorn of Antwerp, Ohio) who had never been south of the Ohio River. He had amebic dysentery in an advanced stage and died a few weeks after entering the hospital, in spite of everything that was known in the way of treatment at that time. This included, of course, ipecac, used as energetically as possible, carried past the stomach in specially prepared capsules. The necropsy showed the colon to be completely denuded of its mucosa over remarkably extensive areas, some of which were certainly 6 or 8 inches long.

The diagnosis is perfectly easy and should be made from stools obtained by a saline laxative, two or three stools being examined on the warm stage immediately after being voided. The presence of actively motile amebas, together with the symptoms of chronic intestinal irritation, should leave no doubt as to the proper diagnosis.

A differential diagnosis between the pathogenic and nonpathogenic amebas found in the intestines is not so easy from a study of morphology alone. The *Entamoeba coli* is the ordinary non-pathogenic form frequently found in healthy persons, its distinctive feature being that it multiplies from daughter-cysts contained within the body of the ameba, the daughter-cysts in this species being eight in number. The *Entamoeba tetragena* contains four instead of eight of these daughter-cysts and is pathogenic. The only other recognized pathogenic form is the *Entamoeba histolytica*, which multiplies by a budding process instead of by the development of daughter-cysts within the organism. Darling[2] in a recent communication maintains that this is a spurious form derived from the *Entamoeba tetragena*. Craig,[3] however, following Schaudinn, maintains the autonomy of *Entamoeba histolytica*. We need not worry about these controversies because the simple fact is that the occurrence of chronic diarrhea with any actively motile amebas present in the stool is sufficient to establish the diagnosis.

Several points seem worthy of comment. The occurrence of marked general abdominal distress, beginning on the second day of treatment and lasting several days, is probably to be referred to the specific action of the emetin on the myriads of amebas with which the intestinal wall was undoubtedly infiltrated. It was probably due to the liberation of endogenous toxins from the killed amebas, acting on the neurovascular mechanisms of the intestinal area. Another interesting feature was the rapid development of severe nausea and vomiting fifty-six hours after a dose (the third) of emetin. It is scarcely supposable that the nauseant and emetic action of the emetin, given hypodermically, could be delayed so long. Pharmacologists tell us that it is rapidly excreted by the gastro-intestinal, and to a less extent by the urinary tract. Here again, I believe the most plausible explanation to be the liberation of excessive quantities of endogenous toxins from killed amebas. It did not occur during the treatment of the relapse, when, it can be fairly assumed, there was only a fraction of the number of amebas present at the outset of treatment.

The tendency to recrudescence is well shown in this case, and we made a mistake in stopping treatment on September 13. Baermann and Heinemann[4] also emphasize this fact, and recommend after-treatment at intervals of three or four weeks, checked by examination of the stools for several months.

Blood examination made Nov. 21, 1913, showed leukocytes, 9,000; polymorphonuclears, 69; small lymphocytes, 28; large lymphocytes, 2; transitional, 1; eosinophils, none. Two important clinical facts are noted, first the disappearance of the leukocytosis, and second the complete disappearance of the eosinophilia, the latter being especially important.

A CASE OF MERCURIC CHLORID POISONING DUE TO VAGINAL DOUCHES

FENWICK BEEKMAN, M.D., NEW YORK

Numerous cases have been reported of mercuric chlorid poisoning by absorption through the vaginal mucous membrane. Most of these have been the result of ignorance, as when a woman has inserted an "antiseptic" tablet into the vagina with a resultant gangrenous inflammation and absorption through the damaged tissue of the part. Other cases of poisoning have been due to douches given to women after childbirth, when absorption is facilitated by the relaxed and abraded tissues.

The case I report demonstrates that the normal vaginal mucous membrane also may in certain persons absorb enough corrosive sublimate from comparatively dilute solution to cause toxic symptoms.

REPORT OF CASE

History.—Mrs. B., aged 22, married six months, has always been healthy with the exception of the usual diseases of childhood. Her menstrual history has been normal; she has not become pregnant. Three weeks prior to examination the patient first noticed a swelling in the legs, though for a month previous she had been conscious of an increase in body size and slight headache had occurred. She consulted a physician who told her she had a chronic "Bright's" and that nothing could be done for her. On further questioning it was found that ever since her marriage she had been using vaginal douches four or five times a week to prevent conception. These consisted of a mercuric chlorid solution, from 1:1,000 to 1:2,000 in strength, made by placing a 7.3 grain tablet of corrosive sublimate in a quart douche-bag from one-half to three-quarters full of water.

Physical Examination.—Patient rather stout with a waxy pallor of skin and mucous membranes and marked anasarca of the entire body. Edema under eyes, which were very prominent and had a "popping-out" appearance. Thyroid not enlarged; no tremor. Heart signs negative; pulse 112, regular, without increased tension and showing no thickening of vessels. Lungs normal. Abdomen prominent with many striae on the skin: percussion note tympanitic over the anterior portion with shifting dulness in flanks; a wave of fluctuation present; edges of liver and spleen not palpable; vaginal examination negative; marked edema of the legs; temperature normal.

Urine (analysis of 1,000 c.c.) dark amber. Specific gravity of 1.004, reaction acid. Albumin 8 grams to the liter (Esbach). Many hyalin and granular casts and red blood-corpuscles.

Systolic blood-pressure 115 mm. of mercury. Blood: hemoglobin 80 per cent., white blood-cells 9,600.

---

[2] Darling, Samuel J.: Budding and Other Forms in Trophozoites of Entamoeba Tetragena, Arch. Int. Med., May 15, 1913, p. 495.

[3] Craig, Charles F.: The Relation of Parasite Amoebae to Disease, Am. Jour. Med. Sc., January, 1913, p. 83.

[4] Baermann and Heinemann: Abst. Am. Jour. Med. Sc. October, 1913.

With the cessation of the douches improvement set in rapidly, the urine output was easily raised to between 2,000 and 3,000 c.c. daily; the anasarca disappeared and the amount of albumin rapidly decreased. At no time did the systolic blood-pressure rise higher than 120 mm. of mercury. In five months she was discharged cured with no signs of her former illness and has since remained well for two years.

This case is of interest because it appears to be one of irritation of the kidney due to the absorption of mercuric chlorid through the vaginal mucous membrane. The amount of the drug absorbed each time must have been small but enough to keep up a constant irritation to the renal parenchyma, for as soon as the douches were discontinued improvement set in and continued until the lesions were apparently cured. Though the symptoms of intestinal irritation and stomatitis were absent, the case must be considered one of mercurial poisoning for the following reasons: The absence of any other factor which might have produced the nephritis, the rapid improvement and cure on cessation of the douches and the typical symptomatology of a toxic nephritis.

It is known that certain individuals are more susceptible to bichlorid of mercury than others, but even though this be so, it is hard to conceive that absorption could take place through the intact vaginal mucous membrane adequate to produce toxic symptoms. Of course where the drug is sufficiently concentrated to destroy tissue, absorption is thereby greatly increased and we may expect toxic symptoms, and as previously remarked in postpartum cases absorption is increased by the retention of the drug due to the relaxed condition of the birth-canal, lacerations and abrasions.

The conclusion, therefore, is that the indiscriminate use of corrosive sublimate as a vaginal douche may be dangerous at any time and this danger is increased if there be any condition present which would tend to increase retention and absorption of the drug.

55 East Sixty-Fifth Street.

DEFACED TYPE OF ADDISON'S DISEASE

Albert O. Holmes, M.D., Long Beach, Cal.

History.—The patient was a Civil War veteran aged 72, seen in consultation with Dr. B. M. J. Conlin of this city. The history up to two years ago had no bearing on the case. The present illness seemed to begin about two years ago with indefinite stomach trouble and indigestion. He had considerable sour stomach and intestinal upset, with attacks of diarrhea, and a very few attacks of vomiting. There was no history of vomiting blood or passing blood by the bowel. He became "run down" and unable to attend to business. For the last six months he has had a yellowish-looking skin and became progressively weaker. The last two weeks he has been confined to bed, during which time he has had chills and fever nearly every day.

Examination.—This showed a very emaciated man with a peculiar lemon-yellow pigmentation of the entire body so often seen in pernicious anemia and sometimes in cachectic conditions due to cancer. Examination of the lungs revealed dulness over the right lower lobe behind, with decreased breathing and fine moist râles, but was otherwise negative. The heart borders were normal, the rate regular, and 78 to the minute. The heart-sounds were very weak and distant, and no murmurs were heard. The abdomen was scaphoid and soft. The liver area was normal, the spleen not felt, the kidneys not palpable; no tumors or enlarged lymph-nodes were discovered. The temperature was 102.2 F. although the heart-rate was only 78, the pulse being of good quality and well sustained. Blood-pressure was 110. Urine examination was negative for albumin, casts, sugar and bile pigments. Blood examination showed: red cells, 1,210,000; white cells, 4,088; hemoglobin, 45 per cent.; color-index, 1.8. The red cells showed marked anisocytosis and poikilocytosis. There were many megalocytes, the average size of cells being above normal. No blast-cells were found, but there were considerable polychromatophilic changes and basophilic granulation. No differential white count was made, but the slides showed a definite relative lymphocytosis. There were no malarial parasites present. A blood examination eight days later showed: red cells, 1,250,000; white cells, 2,482, with same changes as noted above; no blast-cells.

As the patient was very weak and a passage of the stomach-tube was objected to, no gastric analysis was made.

The diagnosis seemed to be one of two things. The color of the skin and the blood-findings strongly suggested pernicious anemia; but the history and the physical findings other than the blood did not bear it out. The history and emaciated appearance of the patient pointed toward cancer of the stomach with a severe secondary anemia. The fact that no tumor could be felt in such an emaciated man clouded the diagnosis of cancer. Addison's disease was not thought of.

During ten days the patient was under observation he had an intermittent temperature ranging from 102 F. to below normal. During the fall of fever he would have drenching sweats. He became progressively weaker and died in coma.

Necropsy.—This was performed thirteen hours after death but the body had been injected with embalming-fluid. In brief the necropsy disclosed the following: The peritoneal cavity was normal and contained no fluid. Pleural cavities contained no fluid; a few adhesions were found at the left apex and many adhesions at the right lower lobe. Pericardial cavity was normal. Heart-muscle was of normal thickness and color; there was some sclerosis of the mitral and aortic valves, but both were competent. The aorta and coronary arteries were slightly sclerosed. The left lung was normal except for a few scars at the apex. There were no tubercles. The lower lobe of the right lung was congested and streamed with bloody, slightly frothy serum on section. The liver and spleen were normal. The kidneys were slightly below normal size and showed some sclerotic changes; the capsules stripped readily; there were no cysts. The left kidney was lobulated. The stomach and intestines were normal. There was no tuberculosis of the mesenteric or retroperitoneal lymph-nodes. The left adrenal was small and adherent and reduced to a caseous cyst. The right adrenal small and caseous in the medullary portion, with a shell of recognizable adrenal cortical tissue. Under the microscope the changes were shown to be tuberculous, with complete destruction of the left gland and partial destruction of the right gland, which contained some apparently normal tissue. The only tuberculous lesions found outside the adrenals was a slight puckering and slight calcareous infiltration at the apex of the left lung.

Such defaced types seem impossible of diagnosis except at necropsy. The most interesting points were the light yellow, pernicious anemia-like pigmentation, and the marked anemia of primary type. The blood-pressure also was not markedly low, and is probably to be explained by the hypothesis that other chromaffin cells of the so-called chromaffin system supplied part of the necessary pressor substance which we designate as epinephrin.

6 Moody Building.

Empyema with Calcareous Pleura.—The patient, an Armenian woman aged 52, a resident of Cesarea, had been treated for the past six or eight months for pleurisy. When I first saw her she was suffering from cough and fever, the temperature being 101.4. Examination of the chest revealed a dulness posteriorly on the right side at the base of the pleural cavity. Exploratory puncture disclosed a quantity of pus. The patient was taken to the hospital and resection of rib performed. About 10 ounces of pus were evacuated, after which digital examination of the pleura showed it to be absolutely fixed, immovable and of stony hardness. Several pieces of this stony plate were broken off at the most dependent part and rubber-tube drainage established. The broken fragments show a deposit about ⅛ inch in thickness and of ivory hardness. The calcareous deposit as a whole is one solid plate about the size of the palm of one's hand. The case illustrates a supreme effort of Nature to wall off a pus cavity in the chest.—A. R. Hoover, M.D., Falas, Turkey.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

DISINFECTANT KRELOS, MULFORD—Krelos.—Mulford disinfectant krelos is said to be a solution of cresols or higher phenol homologues and rosin soap. It is stated to represent approximately: water, 15 per cent.; sodium oxide, 3 per cent.; pyridin, 1 per cent.; rosin acids, 20 per cent.; phenols, 23 to 25 per cent., and hydrocarbons, 36 to 38 per cent.

Actions and Uses.—Mulford disinfectant krelos is an antiseptic, germicide and deodorant.

It is said to be indicated wherever antiseptics or disinfectants are employed.

Manufactured by the H. K. Mulford Co., Philadelphia. No U. S. patent or trademark.

Mulford disinfectant krelos is said to be prepared by addition of coal tar distillates to a rosin soap solution.

It is a dark brown, almost black, liquid, having a specific gravity of about 1.066 and a characteristic cresol-like odor. With water it forms an almost white milk-like emulsion.

The bactericidal power of Mulford disinfectant krelos is determined by the Hygienic Laboratory method. The phenol coefficient, ranging from 5 to 7, is stated on the label.

ANTI-ANTHRAX SERUM.—
H. K. Mulford Co., Philadelphia.

Anti-Anthrax Serum, Mulford.—Anti-Anthrax Serum Mulford is prepared by immunizing horses against virulent anthrax bacilli. At least 80 to 100 Cc. should be injected intravenously as the initial dose. Marketed in packages containing two Mulford aseptic glass serum syringes of 10 Cc. each.

ANTISTREPTOCOCCUS SERUM.—
H. K. Mulford Co., Philadelphia.

Antistreptococcic Serum Scarlatinal, Polyvalent.—It is stated to be the serum of horses which have been treated with streptococci taken from scarlet fever cases. Marketed for immunizing purposes in syringes containing 10 Cc. Dose: 20 to 80 Cc.

Therapeutics

BOILS

Furuncles are probably due to an infection, that is, to pathogenic micro-organisms, and the bacterium which most frequently causes this condition is the *Staphylococcus aureus*, a very rapid-growing organism. While this infection is usually local, very frequently it becomes general, as evidenced by crops of boils.

While a patient's general condition should always be investigated and the urine examined to ascertain whether or not nephritis or diabetes is present, very frequently no systemic disturbance is found. Still, it is good treatment to cause free daily movements of the bowels, to modify the food or even temporarily to change it radically, and to give such tonic treatment as is indicated. That is, gastro-intestinal indigestion should be prevented if possible, iron should be given if needed, and often quinin seems of advantage.

If the patient has suffered from a series of boils there is either some general infection, or the patient's ability to inhibit the growth of the organism is insufficient. The treatment now often found satisfactory is the development and use of an autogenous vaccine. Many times, however, a modification of the diet, the giving of tonics, and the administration of yeast are quickly successful in preventing the repetition of furuncles. The yeast should be taken once or twice a day, depending on its laxative effect. While brewers' yeast was long advised, it acts no better than does the ordinary compressed yeast-cake. The dose is about one-third of a cake dissolved in a glass of water and taken once or twice a day. This sour drink is not disagreeable to most individuals. The exact action of the yeast has not been determined, but it seems to be of value in many infections. Primarily it may change the flora of the intestine somewhat, and secondarily its nuclein content may stimulate the formation of the polynuclear leukocytes of the blood. It also may stimulate the formation of an antiferment that is an aid in killing off or inhibiting the growth of the infective germs.

Yeast has been frequently advised and seems valuable as a wash for suppurating wounds or ulcerations, and as a vaginal douche, but probably its local action is only that of causing greater cleanliness, that is, removing mucus and pus, and thus preventing the growth of bacteria.

There is, perhaps, no one best local treatment for a boil, but some good suggestions are made by Dr. D. Macfarlan[1] of Philadelphia. He strongly advises against the incision of a common boil before it has reached the suppurative stage. He finds that to incise a boil in its formative stage does not hasten the cure and necessitates many dressings. If a boil is imminent, or has already begun to develop, he advises the application of a well-warmed poultice of bread and milk to which has been added a small amount of yeast. The poultice should not be too hot, as this will kill the action of the yeast, and should be changed three times daily. As soon as there is some softening of the tissues and the abscess is well delimited, which generally occurs in two or three days, a crucial incision should be made and the core removed at the first dressing, if possible. Macfarlan then advises that the wound be syringed and swabbed with potassium mercuric-iodid solution, 1 :2,000, and that wet dressings of the same solution be applied until the part is healed. He thinks that this salt of mercury, while less irritant than corrosive sublimate, is as highly antiseptic and tends to promote healing.

Though the recommendation of bread and milk poultices sounds a little ancient, still this method of applying moist heat and causing local hyperemia is efficient. Many times Bier's hyperemic treatment cannot be applied to the affected part, cupping is very painful and often of questionable value, and while a glycerin paste may sometimes act satisfactorily, it does not hasten the process as well as warm applications.

A warm alcohol poultice, consisting of one part of alcohol and four parts of warm water, applied by means of a mass of gauze covered with oiled silk and bound firmly to the part, is a very satisfactory treatment. This dressing need be changed but twice a day.

Whatever the application, the skin in the region of the boil should be covered with petrolatum or other fat to protect it from irritation, and no application should be made so hot as to injure the skin.

A REVISION OF HYPOTHESES REGARDING ENDEMIC GOITER

There are few fields of epidemiologic investigation in which medical science has not been obliged to contend with inherited beliefs and widely disseminated conclusions regarding the etiology and mode of transmission of the disease in question, even when there has not existed any body of incontrovertible evidence to substantiate the traditional views. This has certainly been true of the supposed connection between the incidence of endemic goiter and the water-supply of the affected region. The alleged water-borne cause of this thyroid disease has attained especial prominence since H. Bircher related the distribution of the endemic malady in the case of Switzerland, where it has long been prominent, to the occurrence of very definite geologic formations. E. Bircher extended the hypothesis with the contention that the etiologic agent is removed from the rock formations in question in the guise of a colloidal organic substance, by the waters flowing from them. To the medical mind, goiter-producing waters thus became established as the sine qua non of endemic goiter. To support this hypothesis, statistics of the incidence of goiter in relation to special types of water-supplies were collected and marshaled to prove Bircher's contentions. Famous instances were cited, notably that of the village of Rupperswil, in which goiter was found to decrease after the introduction of a new water-supply from a different (geologic) source, and that of Asp, an isolated goiter region in the midst of a goiter-free district, where relief was similarly brought about.

These and related observations which spoke for a causal rôle played by the water, and in particular the reports of the disappearance of endemic goiter after alteration in the drinking-supply appeared so convincing, despite the contradictions which they not infrequently encountered, that the subsequent discussion has largely revolved about other features. The question was at once raised as to the nature of the etiologic agent in the water, when the primary contention was accepted as proved. We have referred in the past to the Bavarian reports denying the validity of the first hypothesis, that is, the interrelation of geologic factors and endemic goiter.[1] To-day we can add the results of a further extensive study carried out in the very regions of Switzerland which have been the sources of evidence for many years.[2] They show that when an accurate survey is made the distribution of endemic goiter proves to be entirely independent of rock, soil or water-supply. Regions having geologically comparable water sources show a varying and variable incidence of goiter, and furthermore, certain sections of villages having entirely different water-supplies may show a uniform frequency of the disease. The explanation for the unlike intensity of goiter in the various localities is not forthcoming. The reputed improvements following a change of water-supply, and so prominently referred to by Bircher, are now charged to hygienic reforms rather than altered geologic factors. Geographic features, traffic, etc., appear to be of far greater importance in determining the seat of disease.

It is noteworthy that in affected districts certain families and houses exhibit repetition of the disease. There is some evidence to suggest the possibility of localized infection in the home, for example. A hereditary relationship could not be demonstrated; for the fact that the children of goitrous parents are affected somewhat more frequently than others may be due to other simultaneously acting factors, such as frequency of contact, rather than the inheritance of disease. Females are everywhere more subject to endemic goiter than the male population, though the distinction does not appear clearly until after the age of puberty is reached. It seems not unlikely that the presumable enhanced functional activity of the thyroid in the female renders the gland more susceptible to the noxious agent.

To untangle the distorted evidence and conflicting conclusions of a generation means progress, even if no positive results follow. Nothing is so detrimental to scientific progress as the persistence of an erroneous theory. It diverts the investigator from the more direct road to the truth; and what is equally unfortunate, it sometimes encourages the practitioner to indulge in therapeutic measures which are based on an entirely mistaken conception of disease.

SOME PUBLIC ASPECTS OF THE WOOD-ALCOHOL INDUSTRY

Nearly a thousand cases of poisoning attributed to wood alcohol (mostly due to drinking it) have been reported in the literature since 1893, the date which marks the advent of methyl alcohol of a high grade of purity, like that sold under the trade names of "Columbian Spirits," "Colonial Spirits," "Manhattan Spirits,"

[2] Dieterle, T.; Hirschfeld, L., and Klinger, R.: Epidemiologische Untersuchungen über den endemischen Kropf, Arch. f. Hyg., 1913, lxxxi, 128.

"Pro Spirit," etc. The growing publicity of these distressing facts, accentuated by the agitation which has been widely fostered in print by The Journal among other publications, has directed attention to the danger from wood alcohol to such a degree as to arouse considerable uneasiness in the industries connected with its manufacture. We are informed from trustworthy sources[1] that the business involves the annual production and use of about ten million gallons of the substance with a capital investment in this country of about twelve million dollars in the industry, which employs over three thousand working people. It is interesting, therefore, to note the attitude taken in quarters in which business interests must inevitably permeate the purely humanitarian features that are also concerned. We are reminded that since man began to handle fire he has been utilizing dangerous substances to his own good purposes. It is, of course, true that many of the most useful substances are dangerous and poisonous. Deadly cyanids are used for extracting gold; poisonous strychnin is employed as a heart stimulant; toxic phenol finds wide application as a disinfectant, and corrosive acids are used in multitudinous operations.

Despite this indisputable statement, we cannot overlook the equally cogent fact that there are in all the cases mentioned inherent factors which of themselves limit the probability of harmful results in the uses of these poisons. Either there is an adequate understanding of the great dangers involved, or the applications are as a rule in the hands of experts who may be trusted to prevent untoward results. It is contended that methyl alcohol is used extensively as a valuable solvent and in the manufacture of many important materials, and that its legitimate use should not be prohibited. We may agree with these contentions and still raise the question whether or not in the case of the particular poison under discussion, methyl alcohol or wood spirits, the existing legislation is adequate to prevent those disasters which experience has already demonstrated to occur.

It has been noted that wood alcohol presents a unique case for legislation, not only because of its general resemblance to ethyl alcohol, but especially on account of the word "alcohol," which has a definite meaning to the chemist, but is rather associated in the lay mind with "drink." The dangers, however, are by no means limited to the possibility of introducing methyl alcohol in foods or drinks. When, in 1906, the general agitation for a tax-free, denatured ethyl alcohol brought about hearings before the committees of Congress, the injurious action of wood alcohol on the general health and the eyesight of working people handling it in the industries was strongly emphasized by manufacturers employing it, workmen and experts. In the light of this it is interesting to learn the conclusions and recommendations of an unbiased report primarily arrived at from the point of view of the chemist and the industries rather than the alleged one-sided position of the hygienist. This is now available in the pamphlet on wood alcohol prepared for the New York State Factory Investigating Commission by Charles Baskerville, chairman of the Committee on Occupational Diseases of the American Chemical Society.[2] The report does not attempt to pass final judgment on the once debated question which has already been discussed in The Journal,[3] namely, whether the morbid action of wood alcohol is due to the concomitant impurities or not. Economic reasons prohibit the extended use of chemically pure methyl alcohol in the arts and manufacturing industries, although the purest material is now used in certain products. The abuses of methyl alcohol prior to the more recent activity in the direction of pure foods and drugs must be admitted, and likewise the undoubted toxicity of the methyl alcohol of commerce.

There are at present sixty-three manufacturers of wood alcohol in the United States. In their plants the workmen are liable to come into contact with the vapor—one of the modes of intoxication—only in neutralizing the acetic liquor with lime and in filling the shipper containers. Baskerville maintains that general requirements for ample ventilation should meet these difficulties which, in fact, do not now exist in the works inspected in New York State. In the industries in which wood alcohol is employed it often serves as a solvent. Here it can exert deleterious action if the workmen (1) inhale the vapor; (2) dip their hands and arms into the liquor, or (3) drink it. Ample ventilation will avert the first danger; impervious gloves will prevent the second; only education can ward off the third. The precautionary measures are summarized in the New York report in the following recommendation as to laws which should be enacted if not already on the statute books:

1. To prohibit the presence of wood alcohol in any form of material intended for internal use.
2. To prohibit the presence of wood alcohol in preparations intended for external use on the human body.
3. To require ample ventilation in works in which wood alcohol is made or used in manufacturing products wherein the wood alcohol remains as such; the same law should apply where the products containing wood alcohol are used up, as for example, in varnishing vats in breweries.
4. To require containers in which wood alcohol is marketed to bear suitable display labels of warning.

After all is said, the fact remains that the manufacture and sale of Columbian Spirits and other forms of so-called "deodorized" methyl alcohol is a menace to the health of the people and ought to be suppressed. There is no valid argument for permitting its manufacture so long as an effective and cheap substitute exists.

RHEUMATISM AND TUBERCULOSIS

To the physician of a past generation the term "rheumatism" implied an affection or group of affections characterized by certain common qualities, the chief of which were pain, an inclination to attack the joints and muscles, and a dependence on disordered metabolism. From this rather vague group certain diseases have been definitely set off as depending on specific causes. Among these the action of the gonococcus and streptococcus is now generally recognized. It was due to the persistent labor of the late Antonin Poncet that the dependence of a large group of cases on tuberculosis became recognized. He taught that a considerable number of cases of arthritis were due to tuberculosis in which no tubercles could be found, and in some cases the bacilli were only sparsely represented or might be absent. In the latter case the inflammation was attributed to the toxin of tuberculosis. Other observers have confirmed the findings of Poncet, but the frequency of this form of tuberculosis has not been appreciated generally. The opportunity to demonstrate such a lesion by anatomic research is not readily afforded, because after death from tuberculosis, the presence of tubercle bacilli in the fibrous tissues possesses little significance and cannot be brought readily into etiologic relations with past rheumatic or arthritic symptoms. Stock[1] undertook to procure evidence of the tuberculous nature of many so-called rheumatic diseases of the eye by means of the tuberculin reaction. For this purpose he made use of the focal reaction after injection of old tuberculin. He sought to obtain objective evidence of a reaction in the eye in addition to the subjective sensations of the patient. He found in positive cases pericorneal injection, injection of the ciliary vessels and other signs of local action. In a series of seventy-six cases of so-called rheumatic iritis, iridocyclitis and chorioiditis he found a general reaction to tuberculin in forty-five, and in seven of these, distinct focal signs were present.

Sons[2] has recently applied this method to the examination of rheumatic patients, testing them by means of focal signs in the affected joints. In thirteen cases of rheumatic joint affection he obtained a general reaction in eight cases and an organ or focal reaction in eleven cases. The joint symptoms were so limited to the previously affected joints and so different from the joint pains that form a part of the general symptoms of the reaction to tuberculin that he concludes that they indicate the tuberculous nature of the arthritic disease. He found a general and focal reaction in one case of acute articular rheumatism. In this case he succeeded in demonstrating the presence of tubercle bacilli in the blood. In some cases of apparent tuberculous rheumatism a marked improvement took place after the use of tuberculin.

The importance of this subject makes it necessary to weigh with unusual care the evidence in favor of the tuberculous nature of these cases of rheumatism. Reports of the occurrence of tubercle bacilli in the blood have been frequently made since the startling revelations of Rosenberger in 1909. Most of these reports have been made only on the results of microscopic examination. Several authors have shown fallacies in this method, and recently Kahn[3] has shown from experiments with large quantities of blood that both fibrin and the red blood-cells will leave residues, especially after being treated with antiformin, which are acid-fast and may easily be mistaken for tubercle bacilli. He concludes that animal experiment is the only method by which positive proof of the presence of tubercle bacilli in the blood can be furnished. His own experiments showed that the occurrence of these organisms in the blood is much rarer than has been supposed. Kachel[4] expresses a similar opinion. The evidence of the tuberculin reaction may be taken as indicating a tuberculous focus somewhere in the body, and the focal reaction is usually conceded to point to the affected organ. Hence the evidence for the tuberculous nature of the cases investigated by Sons appears to be convincing; but the fact that joint pains and swellings are common effects of bacterial toxins and especially form a part of the general reaction against tuberculin makes it necessary to be cautious in accepting even this evidence without ample confirmation. As the material is abundant and the subject an important one, we may hope that a positive decision of the question may not be long delayed.

THE CULTURE OF MEDICINAL PLANTS

The medical profession has long appreciated the desirability of reliable methods of standardizing those drug products which are prepared in comparatively crude ways from "raw materials" such as parts of plants, and decided advances have been made in securing some uniformity of composition and certainty of pharmacologic efficiency in the case of certain widely used extracts and tinctures derived from plant sources. The preparation of isolated "principles" and the separation of the active therapeutic agents from vegetable (and more recently from animal) tissues have marked a step in advance; but the products of the pharmacy, in distinction from those of the chemical laboratory, are too complex and, as yet, still too little understood, to be completely identified so readily with synthetic drugs or extracted alkaloids. So long as there are justifiable grounds for suspecting that not all the pharmacologic and therapeutic effects of the known constituents of medicinal plants are exhibited in certain tinctures and 'fluidextracts' made from these plants, the latter must continue to receive appropriate attention. This is not a plea for unlimited polypharmacy; it is a logical conclusion springing from the limitations of scientific knowledge in the face of clinical observation. An additional occasion to be concerned for the plants arises from the fact that in many cases they form the sole profitable source of the purified, isolated drugs of commerce.

[2] Sons, E.: Organreaktionen mit Kochschen Alttuberkulin bei klinisch Nichttuberkulosen mit besonderer Berücksichtigung der "asthenischen" und "rheumatischen" Erkrankungen, Beitr. z. Klin. d. Tuberk., 1913, xxviii, 251; abstr., The Journal A. M. A., Nov. 8, 1913, p. 1855.

[3] Kahn, E: Secondary Tuberculosis, Beiträge zur Klinik der Tuberkulose, 1913, xxviii, No 2.

[4] Kachel: Tubercle Bacilli in the Blood-Stream, Beiträge zur Klinik der Tuberkulose, 1913, xxviii, No. 2.

The culture of the medicinal plants, therefore, deserves greater consideration than has been accorded to it in the past. Although agricultural science has for many years devoted much energy to the elucidation of the relations between soils and plant crops and to the application of advantageous fertilizers, and has within recent years been largely concerned with the improvement of crops by the application of the methods of plant-breeding, the medicinal plants have almost without exception received the indifference which is shown to "wild flowers." Practically no serious attempts have been made in this country to extend the best methods of modern agricultural research to drug plants with a view to improving their medicinal qualities. The culture of tobacco illustrates what purposeful field technic can do to change the chemical composition of a species;[1] and the story of the enrichment of the sugar content of the sugar-beet by appropriate selection furnishes an even more striking illustration.

The Office of Drug-Plant and Poisonous-Plant Investigations of the Federal Bureau of Plant Industry has long recognized the necessity that exists for the improvements just referred to; and steps have been taken to inaugurate work in this direction. An interesting instance of the situation that obtains at present is furnished by a study of the belladonna plant, *Atropa belladonna,* probably the most important of the group of solanaceous plants which depend for their therapeutic action on mydriatic alkaloids.[2] We are informed that the supply of this plant in the wild state is largely exhausted, and future supplies must necessarily depend on cultivation. If the hopes for the future are based on the actual facts of the past we may confidently look for great progress to be made in this direction. The government chemical biologist, Dr. Sievers, informs us that thus far nothing has been found to indicate any correlation between the physical appearance of the plant and the alkaloidal content of its leaves. Luxuriant growth is by no means a criterion of the medicinal value of a plant. One may easily be prepared for this conclusion in view of the fact that many of the drugs or alkaloids represent intermediate products in the metabolism of plants; so that an influence which interferes with the natural growth (as when the tops of the tobacco-plant are removed) may actually lead to an abnormal accumulation of a pharmaceutically desired product which would, in the course of unhindered growth, be converted into other substances.

The variations in the percentage of alkaloids in the leaves of different belladonna plants is exceedingly large. This makes it a difficult matter to determine to what extent soil and climate influence the development of the alkaloids. Where such wide variations exist among individual plants the testing of a general sample from all plants collectively is not always a safe means of judgment. There are certain indications that promise to lead to success in the pursuit of appropriate methods of culture. For example, a considerable number of plants with leaves rich in alkaloids in one season are found to have equally rich leaves in the following season. Furthermore, they frequently manifest the same characteristics at the various stages of growth during the season, in comparison with other plants. We are glad to record these beginnings toward the application of the methods of selective breeding, not only because they promise to lead to a way out of the present chaos in respect to the chemical composition of medicinally important economic plants, but also because they may serve to awaken a more wide-spread concern for an important work of the immediate future.

MEDICAL SUPPORT OF THE ANTIVIVISECTIONISTS

Antivivisectionists are usually able to secure a few men who possess the M.D. degree to appear at their meetings and state that experiments on animals are useless. Naturally, because of its scarcity, the testimony of such persons is greatly prized by the opponents of experimentation, and much is made of their professional standing. At the recent International Antivivisection Congress in Washington, "Dr. Richard Cowen, F.R.C.S., London," was on the program for a paper entitled "Vivisection Misleading." What he said was quoted widely in the newspapers, and he was pointed out as an "eminent authority," a "noted savant" and a "big surgeon," who denounced vivisection and declared that it had not added to knowledge of disease.

Investigation has shown that Mr.—not "Dr."—Cowen is only a licentiate of the Irish colleges, that he is not a fellow of the Royal College of Surgeons, London, and that he is not attached to any hospital except a small place in southwest London which has twenty-three beds. In other words, the professional status ascribed to him again illustrates the carelessness of antivivisectionists about telling the truth. There are, of course, some men, usually with bizarre medical training, who are impervious to evidence, and, like the strange persons who argue that the earth is flat, "stand pat" with the middle ages. Such persons set themselves against all the methods that have yielded the triumphs of modern treatment and sanitation.

[2] Sievers, A. F.: Individual Variation in the Alkaloidal Content of Belladonna Plants, Jour. Agric. Research, 1913, i, 129.

Against the testimony of these few benighted medical men are the laboratories for animal experimentation connected with medical schools, hospitals, boards of health, government bureaus and privately endowed institutions for research. Against them also are all the means taken by governmental authorities for the preservation of public health — means based almost directly on the results of animal experimentation. Against them also is the overwhelming conviction among enlightened physicians and surgeons that animal experimentation has been and must continue to be of the utmost importance to the advancement of medicine.

The recent International Medical Congress (in London, 1913), composed of representatives from the entire civilized world, passed with only one dissenting vote (that of a woman physician) the following resolution:

> *Resolved*, That this congress records its conviction that experiments on living animals have proved of the utmost service to medicine in the past, and are indispensable to its future progress. That accordingly, while strongly deprecating the infliction of unnecessary pain, it is of opinion, alike in the interests of man and of animals, that it is not desirable to restrict competent persons in the performance of such experiments.

And in 1908 the two greatest scientific bodies of the United States, the American Medical Association and the American Association for the Advancement of Science, passed without a single protest the following resolutions:

> Whereas, from time to time, attempts, fostered largely by erroneous statements and accusations and false sentiment and prejudice, are made in some parts of this country to enact specific legislation, prescribing the conditions under which experiments on animals may or may not be performed; be it
>
> A. *Resolved*, by the Association, That animal experimentation has been of incalculable benefit to medical science and art, the progress of which is as absolutely dependent on experimental methods as are all the physical and natural sciences.
>
> B. *Resolved*, That no abuse of the practice of animal experimentation in this country has been shown to exist to warrant specific legislation, nor is there any probability of such abuse arising.
>
> C. *Resolved*, by the Association, That the unrestricted performance by proper persons of scientific experiments on living animals is essential to the maintenance and progress of medicine and biology.

When the antivivisectionists are shouting the name of some obscure doctor who supports their views, their enthusiasm might properly be sobered by the foregoing authoritative declarations.

ANIMAL SPIRITS — NERVOUS IMPULSES

Despite the progress of science and the expansion and more precise definition of knowledge from generation to generation, we still adhere to modes of expression which had their origin in the cruder conceptions of earlier days. Few persons ever stop to consider, when they speak of "a man of spirit," that they are unwittingly employing the language of the days of Galen. Yet this is evidently the survival of the old doctrine of spirits. We may believe that Galen had a conception of the nerve-trunks as conductors of something — he called it spirits — to and from the brain and spinal cord.[1] The natural spirits were that undefined property which gave to blood the capacity of nourishing the tissues of the body. The vital spirits were acquired in the heart; and when at last the blood with its vital spirits went to the brain and experienced a sort of refinement for the last time, the animal spirits were separated from it and carried to the body by the nerve-trunks. Here, then, is the beginning of the modern idea of innervation; the animal spirits of Galen have become the nervous impulses of to-day. The ancient "spirits" in the nerves were converted into the *succús nerveus* of later eras when the rising school of physicists began to center their interest in the properties of fluids which can conduct disturbances without themselves traveling. Subsequently it was the *vis nervosa* of Albrecht Haller that furnished the stimulus to the muscle. For a time this was identified with animal electricity. In the present day we express the same underlying conception by the term "nervous impulses." These are not electricity, but they produce it and can be manifested by it. As Harris[1] has said, each generation must think and express itself in the language of its own time.

THE CORONARY CIRCULATION

Precisely like every other muscle, the heart must be profoundly influenced in its working capacity by the character and abundance of the blood-supply which it receives. Owing to the perfection of modern experimental technic it is now possible to study the contractile efficiency of the heart quite independently of the rest of the body. Some of the agencies which tend to affect it have been determined by Markwalder and Starling,[2] who have found that the coronary circulation is intimately dependent on the arterial pressure. In confirmation of other workers, they also find that epinephrin causes dilatation of the coronary vessels, thus giving the weight of added authority to this solution of a somewhat debated question. Obviously it is a matter of no little importance to know in what sense the circulation and hence the nutrition of the cardiac musculature are influenced by alterations in the chemical composition of the blood which traverses it. Carbon dioxid was found to have the same effect on the coronary vessels as on the other blood-vessels and the heart, namely, relaxation or dilatation. In asphyxia the circulation through the heart is decidedly augmented. In fact, whenever the heart is failing, the circulation through its vessels is increased, and this increase may be marked even when the aeration of the blood is well carried out so that no opportunity is allowed in it for the accumulation of carbon dioxid. Under the conditions giving rise to asphyxial and related conditions of the cardiac tissue it is more than probable that non-volatile metabolites are produced by the imperfectly supplied heart-muscle. They are the most potent agents in causing dilatation of the coronary vessels. By this means a local mechanism is supplied by which the heart-muscle will increase the circulation through itself whenever increased demands are made on its functional capacity. This is only another illustration of the almost endless effective adaptations by which the parts of the organism tend to adjust themselves advantageously to changing physiologic conditions.

---

SOUTH CAROLINA TO THE FORE

The *Journal of the South Carolina Medical Association* is the latest medical journal to discard the old régime and join forces with those that represent the newer ideals of medicine. The January number of this journal is clean from cover to cover. Only such medicinal substances as have been passed on and accepted by the Council on Pharmacy and Chemistry are now eligible to its advertising pages. The time should be past when the profession is willing to permit the exploiters of proprietary frauds to pay the bulk of the printing and publishing bills of the medical journals which it patronizes. In South Carolina it evidently *is* past. The South Carolina Medical Association is neither a large nor a wealthy organization, yet it is willing to make a not inconsiderable financial sacrifice for the sake of principle. The physicians of this Southern state evidently believe that the Council, which their society, with other component parts of the American Medical Association, brought into being, should receive the moral support of the profession, even though by so doing their official organ loses some "easy money." South Carolina is to be congratulated.

SANITARY SUPERVISION OF A FLOOD RELIEF EXPEDITION

It has been said that an army marches on its stomach. A modern addition to this adage would be that its effectiveness depends on the health of its units. Industrial organizations, likewise, are learning that attention to sanitation and the care of the health of the individual worker is a first consideration for working efficiency. An illustration of the application of this principle is afforded by a report to the general manager of the Pennsylvania Railroad by the superintendent of an emergency relief expedition for repairing damage to the railway in the tremendous floods in western Pennsylvania, Ohio and Indiana in 1913. The floods caused the destruction of miles of tracks and scores of bridges, and railway traffic was almost absolutely suspended in the entire flood region. The enormous damage wrought to the Pennsylvania lines is graphically described and illustrated in a pamphlet issued by the Pennsylvania Company. To open up the roads in the quickest possible time not only required all the resources at the command of those involved, but also compelled them to accept the proffered assistance of other roads. The Long Island Railroad sent a relief party to the Pennsylvania Lines west of Pittsburgh under the command of Superintendent Thornton, comprising over seventy men skilled in emergency railway repair work, with the company surgeon, Dr. J. Kent Worthington, as sanitary and medical officer. The wisdom of providing for the sanitary supervision of the expedition is shown in the outcome. A complete outfit of medicines, bandages, instruments, etc., to meet almost any emergency was provided, of course, but outside of a few minor accidents, little work in this line was required during the period of about a month which the relief party spent in this work. The chief duties of the medical officer were of a preventive character, and included close supervision of the food-supply and its preparation, the water-supply and the camps and bunk-cars, the latter being kept thoroughly cleaned and disinfected, with proper attention to ventilation, etc., and the inspection and examination of all wells or other sources of water-supply before any water was allowed to be used. Each member of the party was personally inspected and questioned each day by the medical officer as to his condition, and approaching trouble was immediately attended to. In addition, the physician lent his assistance to the work of the communities in which he was stationed. The outcome of this care of the men was that the expedition returned home with every man in better physical condition than when he started, as the result, the superintendent says, of this careful supervision of the medical officer. The superintendent in his report makes the general observations that he considers the presence of a medical man with an expedition of this sort as absolutely essential to its efficient work; that the theory of this is thoroughly recognized in military affairs; that there is no reason why it should not apply to other classes of work of a similar character, an army, a football team or a railway force, and that unless the members of an expedition, whatever it may be, are kept in good physical condition, inefficiency will result. This represents the application to industrial affairs of the principle of sanitation first which permitted the building of the Panama Canal.

INDUSTRIAL SANITATION IN THE TROPICS

Not only the railroads of this country, but also the great tropical plantation companies have found it profitable to apply to their enterprises the principles of modern sanitation, thereby keeping the death-rate among their employees at a point that compares favorably with the rates of communities more favorably situated. The methods employed are efficient medical and sanitary organization and the application of the methods demonstrated in the work on the Panama Canal. In its detailed reports of the medical department for 1912 and 1913, the United Fruit Company, one of the largest of these plantation enterprises, with plantations in Panama and other Central and South American countries and in Cuba, with an aggregate of over 65,000 employees, shows some astonishing results. For instance, in the Panama division, for 1912 the average death-rate for the whites among the employees was 12 and of the blacks 11.36 per thousand. In 1913 the death-rate among the whites was 3.33 and for the blacks 7.7, giving a general average of 7.5 per thousand. This extremely low mark was not attained in the other divisions of the company's plantations, but with a splendid sanitary organization, by large expenditures for suitable houses, hospitals, drainage and mosquito elimination, and by periodic visits to all the plantations by physicians, the health has been kept at a high average. The sanitary forces always are first in the field when new plantations are opened up, and all the principles of modern sanitation in the tropics are applied as rapidly as possible. The reports state that this work has not followed in the wake of that on the Panama Canal, but that the work of mosquito elimination and other measures were applied immediately after the demonstration of mosquito transmission of the tropical fevers. The problems involved are difficult and the work is enormous, but this large corporation has found that it pays abundantly. The reports show that the personnel of the medical organization has been drawn from all of the best medical schools in the United States, and constitutes an efficient sanitary force. With the completion of the Panama Canal the large plantations like those of the United Fruit Company will continue to furnish opportunities for the young men from the colleges to gain experience and do research work in the tropical diseases.

SMOKING ON STREET-CARS

Sooner or later, every city large enough to need street-cars has to settle this question: Should or should not smoking be permitted on such cars? In all cars of the closed type—the most prevalent kind—when smoking is permitted it is usually limited to the front or rear platforms. As passengers need to use both the rear and front platforms in boarding or leaving cars, the condition of these parts of the car is a matter that directly concerns the public health. While many cities have antispitting ordinances, these laws are, in the majority of instances, more honored in the breach than in the observance. As a result, the street-car platforms where smoking is permitted become both an offense to the eye and a menace to health. Where smoking is allowed on the front platform, and particularly in that type of car that has the front platform enclosed, the motor-man works from morning until night in a tobacco-smoke-impregnated atmosphere, while the passengers who leave the car by the front platform have to pass through this expectoration-decorated "fume-chamber." When the question, Shall smoking be abolished on street-cars? comes up for settlement with any city, there can be only one answer. From the point of view of hygiene and common cleanliness, to say nothing of the comfort of the majority, smoking on street-cars is an indefensible nuisance.

Memory.—Now and then one learns something, but one forgets the whole day long. Moreover, our memory is like a sieve, the holes of which in time get larger and larger. The older we get, the quicker anything intrusted to it slips from the memory, whereas, what was fixed fast in it in early days is there still. The memory of an old man becomes clearer and clearer, the farther it goes back, and less clear the nearer it approaches the present time, so that his memory, like his eyes, becomes long-sighted.—Schopenhauer.

Medical News

CALIFORNIA

Opening of Polyclinic.—The San Francisco Polyclinic formally opened its new building, which has been erected at a cost of $25,000, and celebrated the twenty-fifth anniversary of the founding of the institution, January 24. The institution now cares for about 600 patients a month at a cost of about $700.

New Officers.—Contra Costa County Medical Society at Oakland, January 19: president, Dr. Ursa S. Abbott, Richmond; secretary-treasurer, Dr. Earl B. Fitzpatrick, Martinez.——Monterey County Medical Society at Salinas, January 9: president, Dr. Garth Parker; secretary, Dr. Hezediah T. Crabtree, both of Salinas.——Fresno County Medical Society at Fresno, January 6: president, Dr. Charles O. Mitchell, Fowler; secretary, Dr. Lamont R. Willson, Fresno.——San Joaquin County Medical Association, at Stockton, Dec. 26, 1913: president, Dr. John D. Dameron; secretary, Dr. Raymond T. McGurk, both of Stockton.——Long Beach Branch of the Los Angeles County Medical Association, Dec. 12, 1913: president, Dr. Wilmer L. Dickerson, Long Beach; secretary-treasurer, Dr. C. G. Foote.

DELAWARE

Hospital to Be Enlarged.—The Physicians and Surgeons Hospital, Wilmington, is to be enlarged by an addition to cost $4,200.

New Officers.—New Castle County Medical Society at Wilmington: president, Dr. George W. K. Forrest; secretary-treasurer, Dr. Talison H. Davies, Farnhurst.

State Board Reappointed.—Governor Miller has reappointed as the State Board of Medical Examiners Drs. Henry W. Briggs and Abram E. Frantz, Wilmington, and Drs. Edwin S. Anderson and Presley S. Downs, Dover.

Personal.—Drs. Pietro A. M. Rovitti, Napoleon B. Morrison, Bernard A. Jenkins and Harry M. Frist have been appointed vaccine physicians for Wilmington.——Dr. Wilson R. Pendleton, Wilmington, has been appointed superintendent of the State Sanatorium for the Treatment of Tuberculosis, Montrose, N. C.

IDAHO

New Officers.—Bannock County Medical Society, at Pocatello, January 21: president, Dr. Edward N. Roberts; secretary-treasurer, Dr. Joseph V. Clothier, both of Pocatello.

Northern Idaho Physicians Meet.—The first meeting of the Northern Idaho District Association since its organization was held in Lewiston, January 15; the opening address was delivered by Dr. James M. Fairly, Orofino. It was decided to hold the next meeting at Lewiston.

ILLINOIS

New Officers.—Stephenson County Medical Society at Freeport, January 29: president, Dr. Karl F. Snyder; secretary, Dr. J. Sheldon Clark, both of Freeport.

State to Distribute Antityphoid Vaccine.—The State Board of Health announced, January 4, that free vaccine for the prevention of typhoid fever was ready for distribution to all parts of the state.

Personal.—Dr. Ralph T. Hinton, superintendent of the Elgin State Hospital was appointed superintendent of the Peoria State Hospital, February 9, succeeding Dr. Henry J. Gahagan, who has been transferred to the Elgin State Hospital.——Dr. Marcus Whiting, Peoria, who is about to retire from practice and live on a farm in Northern Wisconsin, was given a farewell dinner by the Peoria Medical Society, at which he was presented with a gold-headed cane.——Dr. William Freeman, North Crystal Lake, is reported to be seriously ill with typhoid fever.——Dr. Clesson C. Atherton, Elgin, physician to the Lincoln State School and Colony, has been appointed assistant superintendent of the Watertown State Hospital.

Chicago

Monod in Chicago.—Dr. Gustav Monod, Paris, will speak before the Chicago Medical Society March 4.

Post-Graduate School Reconstructed.—In celebration of the reconstruction of the Post-Graduate Medical School of Chicago, the directors held a reception in the institution, January 22, from 2 to 9 p. m.

Personal.—Dr. Arthur R. Edwards has completely recovered from the appendectomy and cholecystectomy performed January 6, and has resumed practice.——Dr. Charles F. Sanborn has resigned as assistant warden of the Cook County Hospital, and has been appointed superintendent of the Cincinnati Hospital.——Dr. Carl, Koenigsberg, Germany, is to be assistant to Dr. Albert J. Ochsner at the College of Physicians and Surgeons of Chicago. His position in Koenigsberg will be filled by a surgeon from Chicago, who will go to Koenigsberg as exchange lecturer.——Dr. Frank Smithies has been elected gastro-enterologist to the Augustana Hospital.

Housing Conditions in Chicago.—According to the *Bulletin of the Chicago Department of Health*, housing conditions in the city are improving, as far as the construction of new houses and tenements is concerned. But the conditions in the old buildings in the older parts of the city do not show great improvement. In 1913, the department passed 9,788 plans for dwellings and tenements; 38 per cent. of these were for single family dwellings. These are built in outside parts of the city, and are of a very desirable type. It is stated that 77.43 per cent. of the total number of dwellings and tenements erected during 1913 were designed for two families. This means that, under the conditions prescribed for the erection of such dwellings, there is an immense improvement in the matter of air, light and sunshine, which will make for improvement in health conditions. It is also said that of 15,105 apartments, provided in the buildings erected during the year, 96.34 per cent. were provided with bath-tubs.

Health and the Open Winter.—The old-time theory that an open winter was prolific of ill-health seems to be disproved for the present season, in the city of Chicago, at least. The winter has been unusually mild, the thermometer on January 28 recording 60 degrees. There has been practically no snow throughout the months of December and January. According to the *Bulletin of the Chicago Department of Health*, there has been for the eight weeks ending January 24 a reduction of 29.6 per cent. in the pneumonia death-rate as compared with the average of a like period for the previous five years; 23.3 per cent. in influenza and 7.8 per cent. in the rate for tuberculosis. There have likewise been reductions of the incidence of measles, which dropped 82 per cent.; scarlet fever, 54 per cent.; diphtheria, 24.2 per cent., and whooping-cough, 18.2 per cent. The *Bulletin* accounts for this by the opportunity given by the mild weather for out-door living and better ventilation in living quarters. It is estimated that in the diseases named there has been a saving of 515 lives during the six weeks of December and January for which the comparison was made.

INDIANA

New Officers.—Clark County Medical Society: president, Dr. W. B. Marshall Varble; secretary, Dr. Isaac Ruddell, both of Jeffersonville.

Medical Staff Banqueted.—The Sisters of St. Elizabeth's Hospital, Lafayette, entertained the members of the medical staff and the lecturers of the training school for nurses, January 28. Dr. George F. Beasley officiated as toastmaster.

Personal.—Dr. T. Victor Keene, Indianapolis, fractured his left arm when his automobile overturned near Indianapolis, January 30.——Dr. John S. Ragan has been appointed physician at the Indiana Boys' School, Plainfield.——Dr. Joseph R. Bloomer, Rockville, has been appointed local surgeon of the Vandalia system.

Anti-Tuberculosis Society Meets.—The annual meeting of the State Society for the Study and Prevention of Tuberculosis was held at Indianapolis, January 31. Drs. Henry B. Shacklett, New Albany; S. Edgar Bond, Richmond; Fred A. Dennis, Crawfordsville; Eric A. Crull, Fort Wayne, and James A. Snapp, Goshen, were elected directors.

Cost of Care of Insane.—According to the report of the Board of State Charities for 1913, it cost the state $204.79 to maintain each inmate of the five state insane hospitals during the year. At the close of the year there were 6,100 known insane in the state; of these, 5,577 were in public institutions, and 523 in outside institutions; 5,090 were under state care and 1,010 without state care. The board emphasized strongly the overcrowded condition of the state hospitals.

KENTUCKY

New Officers.—Clark County Medical Society at Winchester, January 24: president, Dr. William A. Bush; secretary-treasurer, Dr. Harvey R. Henry, both of Winchester.

New Hospital Turned Over to the City.—The new City Hospital, Louisville, was turned over to Mayor Buschemeyer by the Hospital Commission, February 7. The ceremonies, which were brief, were held in the amphitheater of the new hospital.

To Prevent Blindness.—At the meeting of the Jefferson County Medical Society, January 19, unanimous endorsement was given to the bill introduced by the Kentucky Society for the Prevention of Blindness which provides for a strict report of cases of trachoma or ophthalmia in new-born children.

Personal.—Dr. Lewis S. McMurtry has been elected president of the medical staff of the John N. Norton Memorial Infirmary, Louisville, vice Dr. J. B. Marvin, deceased.——Dr. George W. Lawrence, Louisville, is reported to be critically ill at his home.——In the case of Doretta Hill against Dr. John W. Kremer, Louisville, in which claim for $20,000 damages was made for alleged malpractice and neglect, the judge, after hearing the evidence of the plaintiff, instructed the jury to return a verdict in favor of Dr. Kremer.

Staff for Louisville City Hospital.—The method of the appointment of the visiting, medical and surgical staff for the new City Hospital has been the subject of considerable comment on the part of the profession as the furnishing of the hospital nears completion. The Commercial Club has advocated the passage of a bill by the legislature now in session providing for the control of the new City Hospital by a non-political commission composed of four members with the mayor ex-officio. The mayor, who is a physician, has signified his opposition to this plan of government and has announced that he has placed the medical and surgical control of the City Hospital in the hands of the board of trustees of the University of Louisville, Medical Department. This announcement caused a vigorous protest from an organization called the Medical Club, composed, largely, of physicians not connected with the Medical Department faculty. These objections have been overcome by the announcement by the trustees of the university that the appointments are to be made by a special committee composed of the following: Drs. Ap Morgan Vance, one of the members of the commission that erected the hospital, and Ben Carlos Frazier, representing the non-school men; Drs. Henry H. Grant and William A. Jenkins, representing the faculty of the University, with the assistant dean, Dr. David C. Morton, ex-officio member of the committee. According to the instructions from the trustees to this committee, they are to recommend to the board of trustees, which will turn over the recommendations to the Board of Public Safety for appointment, a staff of physicians and surgeons who are to look after the sick poor as a chief consideration, the teaching portion of the hospital being a secondary consideration. They are instructed to use their judgment in regard to the appointment of members of the medical faculty for the school term and non-school men during the vacation period. The committee will shortly meet and make the selection of the staff to be recommended for appointment by the Board of Public Safety.

LOUISIANA

Hospital to Purchase Policlinic.—At a meeting of the board of directors of the Charity Hospital, New Orleans, January 19, it was decided to acquire the Policlinic property at Tulane Avenue and Liberty Street, using the building for clinical purposes.

Railroads Will Help State Health Board.—At a conference between representatives of the railroads of the state and Dr. Oscar Dowling, a committee consisting of Dr. E. Denegre Martin and J. F. Porterfield was appointed to confer with the board in regard to the reforms deemed necessary.

Medical Society Organized.—At a meeting of the medical men of Acadia Parish at Crowley, January 30, the Acadia Parish Medical Society was organized, and the following officers were elected: president, Dr. David Dougal Mims; secretary, Dr. M. L. Hoffpauir, both of Crowley. The first meeting of the society will be held April 2.

Sanatorium Organized.—The Cooperative Sanatorium Association was organized at Lafayette, January 26, with the following officers: president, Dr. John D. Trahan; vice-presidents, Drs. Frederick R. Tolson and Eric Guilbeau; secretary, Dr. John F. Mouton, and treasurer, Dr. Felix E. Girard. The institution will be named the Attakapas Sanatorium.

New Officers.—Rapides Parish Medical Society at Alexandria, January 5: president, Dr. Robert L. Randolph; secretary-treasurer, Dr. James A. White, both of Alexandria.——Lincoln Parish Medical Association at Ruston: president, Dr. Joseph L. Smith, Dubach; secretary, Dr. William S. Rutledge, Ruston.——Avoyelles Parish Medical Society at Bordelonville: president, Dr. Sambola J. Couvillon; secretary, Dr. Paul E. Brahic, both of Moreauville, both reelected.——St. James Parish Medical Society at Convent: president, Dr. Clifford A. Himel, St. James; secretary-treasurer, Dr. Joseph E. Doussan, Lutcher. ——Orleans Parish Medical Society at New Orleans: president, Dr. Charles N. Chavigny; secretary, Dr. Edward L. King, both of New Orleans.

MICHIGAN

Hospital Notes.—The State Commission has appointed a board of control for the new municipal John F. Eilbert Memorial Hospital, Wyandotte.——The Detroit Board of Health has asked for an appropriation of $1,744,445, of which $1,250,000 is for hospital purposes alone.

Personal.—Dr. John L. Burkart, Big Rapids, assumed charge of the office of secretary of the State Board of Health, February 2, succeeding Dr. Robert M. Dixon, Lansing, who has assumed his new duties as superintendent of the State Home for Epileptics.——Dr. Louis H. Chamberlin, Grand Rapids, left for Europe February 1.——Dr. and Mrs. L. J. Pelletier, Ludington, returned from Europe this month.

Detroit Pediatrists Organize.—The Detroit Pediatric Society held its first annual meeting January 28, and elected the following officers: president, Dr. Thomas B. Cooley; vice-president, Dr. Herbert M. Rich; secretary-treasurer, Dr. Francis Duffield. The society is to hold eight regular meetings each year, and the membership is composed of active members, limited to twenty, associate members and honorary members.

New Officers.—Delta County Medical Society, at Escanaba, January 20: president, Dr. James Mitchell, Gladstone; secretary-treasurer, Dr. Harry W. Long, Escanaba.——Houghton County Medical Society at Houghton: president, Dr. Peter D. MacNaughton, Calumet; secretary-treasurer, Dr. Isadore D. Stern, Houghton.——Muskegon-Oceana Counties Medical Society, at Muskegon, January 2: president, Dr. Jacob Oosting; secretary, Dr. Jacob T. Cramer, both of Muskegon. ——Hillsdale County Medical Society at Hillsdale, Dec. 30, 1913: president, Dr. Burt F. Green; secretary-treasurer, Dr. Charles T. Bower, both of Hillsdale.——Ionia County Medical Association at Ionia: president, Dr. Harry B. Knapp; secretary, Dr. John J. McCann, both of Ionia.——O. M. C. O. R. O. (Otsego, Montgomery, Crawford, Oscodo, Roscommon, Ogeman) Counties Medical Association, at Grayling: president, Dr. Frank E. Abbott, Sterling; secretary, Dr. Robert J. Beebe, West Branch.

MINNESOTA

Personal.—Dr. C. L. Blunt has returned after eight months in Bangkok, Siam.——Dr. C. A. Scherer, Minneapolis, has been appointed intern at Lymanhurst, in charge of the Minneapolis Municipal Tuberculosis Camp which was opened February 1.

Hospital Notes.—A hospital has been established by the physicians of Rush City. The institution occupies the second floor of the Electric Light Building, and will be in charge of a trained nurse.——A bond issue has been authorized by the Minneapolis City Council for the construction of a new hospital for contagious diseases, to be eight stories high, three stories of which will be completed and furnished this year.

War on Tuberculosis.—At a meeting of the board of directors of the State Antituberculosis Association, it was reported that $200,000 has been obtained during the year for the state institution at Walker, which now can accommodate 175 patients. More than $269,000 has been appropriated for sanatoria in Ramsey, Hennepin, Polk, Clay, Becker, Goodhue, Lincoln, Pipestone, Marshall, Lake, Renville, St. Louis, Ottertail, Wabasha, Lyon, Murray and Watonowan counties.

New Officers.—Ramsey County Medical Society, at St. Paul, January 26: president, Dr. John Milton Armstrong; secretary, treasurer, Dr. Charles E. Smith, Jr., both of St. Paul.——Park Region District County Medical Society, at Fergus Falls, January 22: president, Dr. Theodore N. Kittleson, Fergus Falls; secretary-treasurer, Dr. Randall Ashby.——Upper Mississippi Medical Society, at Brainerd, January 6: president, Dr. Frank H. Allen, Staples; secretary, Dr. Francis J. A. Bennet, Brainerd. ——Goodhue County Medical Society, at Red Wing, January 6: president, Dr. Peter H. Cremer; secretary-treasurer, Dr. Alonzo T. Conley, both of Cannon Falls.——Winona County Medical Society, at Winona, January 6: president, Dr. James L. Lynch; secretary, Dr. Hugh F. McGaughey.——Blue Earth County Antituberculosis Society, at Mankato: president, Dr. John W. Andrews; vice-president, Dr. Chelsea C. Pratt, both of Mankato.——Camp Release District Medical Association, at Montevideo, January 29: president, Dr. Herman M. Johnson, Dawson; secretary-treasurer, Dr. Reuben D. Zimbeck, Montevideo.——Brown and Redwood Counties Medical Society, at New Ulm, January 29: president, Dr. Dirk V. Gleysteen, Lamberton; secretary-treasurer, Dr. George F. Reineke, New Ulm.

MISSISSIPPI

Health of the State.—The Mississippi Health Bulletin for the first nine months of 1913 shows that during this period there were 25,641 births, of which 13,967 were white and 11,674 colored. During the same period 15,104 deaths were reported, of which 5,332 were whites and 9,772 negroes. The malarial patients reported were 49,159, almost equally divided between white and colored patients. Tuberculosis during the same time was reported in 3,665 cases, of which 1,583 were whites and 2,062 negroes, the white death-rate from tuberculosis being 6.7 per cent. and that of the negroes 15.1 per cent.

New Officers.—Lauderdale County Medical Society at Meridian: president, Dr. T. D. Bourdeaux; secretary-treasurer, Dr. Albert F. Douglas, both of Meridian.——Hinds-Rankin Counties Medical Association: president, Dr. Robert S. Curry, Jackson; secretary-treasurer, Dr. James H. Fox, both of Asylum, both reelected.——Northern Mississippi Tri-County (Tate, Panola and De Soto) Medical Society at Senatobia, January 29: president, Dr. James M. Jenkins, Crenshaw; vice-president for Tate County, Dr. Bucy; for Panola County, Dr. Albert P. Alexander, Como; for De Soto County, Dr. C. L. Maples, Olive Branch; secretary-treasurer, Dr. William D. Smith, Senatobia.——Meridian Tuberculosis Association: Dr. T. D. Bourdeaux, vice-president.

MISSOURI

New Hospital Opened.—The People's Hospital at Bevier, recently erected at a cost of $35,000, was opened last week. Dr. Terrence P. Gronoway is in charge of the institution.

District Tuberculosis Hospital Law Unconstitutional.—The supreme court has declared unconstitutional the law providing for tuberculosis hospitals, on account of the irregularity of the tax levy.

Personal.—Dr. Robert P. C. Wilson, Platte City, has been elected superintendent of the State Colony for the Feeble-Minded, Marshall.——Dr. and Mrs. Frank A. Lee, Skidmore, started for Honolulu January 12.——Fire in the house of Dr. Horatio S. Jones, Kansas City, did damage to the extent of $1,800.

Sanitary Survey for St. Joseph.—Dr. Joseph H. White, U. S. P. H. S., surgeon in charge at New Orleans, has arrived in St. Joseph to work with the local Board of Health regarding the proposed sanitary survey, which is designed to increase the efficiency of the Health Department, and to obtain better enforcement of health measures.

State Board Election.—The Missouri State Board of Health, January 2, elected the following officers for the current year: president, Dr. Francis H. Matthews, Liberty; vice-president, Dr. Godfrey O. Cuppaidge, Moberly; secretary, Dr. James A. B. Adcock, Warrensburg (reelected).——J. L. Walker, an osteopath of Memphis, has been appointed a member of the State Board of Medical Examiners.

St. Louis

Negroes Want Hospital.—Negroes of St. Louis have started a campaign to raise $30,000 for the erection of a more commodious and modern Provident Hospital.

Doctors' Club Organized.—At the Doctors' Club, which was organized January 16, Dr. Eugene R. Waterhouse was elected president and Dr. Albert F. Stephens, secretary.

Personal.—Dr. Solomon A. Weintraub has sailed for the Mediterranean.——Dr. Walter R. Hewitt, medical director of the United Railways Company, sailed for Europe January 31.

Medical Library Dedicated.—The St. Louis Municipal Medical Library, located in the room originally designed for it at the City Hospital, was dedicated with appropriate ceremonies January 20. The library has already 3,500 volumes.

Quick Work on Small-Pox Hospital.—The addition to the quarantine hospital, south of Jefferson Barracks, for small-pox cases, was built in two days by the Board of Public Improvements. The structure is 22 by 50 feet, and contains two wards, each of which has accommodations for twelve patients.

NEW YORK

The Rural Death-Rate.—The State Grange, at its convention in Poughkeepsie on February 5, pointed out that while the death-rate of New York City is 13.7 per thousand population, towns under 8,000 population have a death-rate of 15.4, and passed resolutions urging the establishment of a division of rural hygiene in the New York State Department of Health.

Inwood Hospital Work.—The Hospital and House of Rest for Consumptives at Inwood-on-the-Hudson cared for 133 patients last year, which were received from various hospitals, clinics, settlements and charitable institutions. Of this number 43 were discharged and 21 died. The total number of days care given was 23,786, an increase of 3,496 over the preceding year. The average stay of each patient was 178.8 days as compared with 147.7 for the year 1912.

Personal.—Dr. Edwin A. Walcott has been appointed chairman, and Drs. Charles L. Barber, Elmer J. Bissell, Loron W. Howk, William B. Jones and Charles R. Sumner members of the Rochester City Public Health Committee.——Dr. Melville B. Dickinson has been appointed chief medical inspector of the public schools of Troy.——Dr. Henry L. Shaw of Albany, has been appointed director of the division of child hygiene of the Health Department of the State of New York, and Dr. Augustus B. Wadsworth of New York has been appointed director of the division of laboratories and research.

To Merge All Medical Societies.—Dr. W. Douglas Ward, president of the Rochester Pathologic Society, has appointed a committee consisting of Drs. William B. Jones, Charles R. Barber, Willis E. Bowen, Ralph R. Fitch, William W. Percy, J. H. Treton, Kathleen L. Buck and David B. Jewett to formulate plans for the union of all medical societies of Rochester and Monroe County and for the erection of a suitable club house. This project will include the Monroe County Medical Society, Rochester Pathologic Society, Rochester Academy of Medicine, Rochester Hospital Medical Society, Rochester Homeopathic Medical Society, Rochester Hahnemann Medical Society and Blackwell Medical Society, the latter an organization of women.

Work of Milk Commission.—The Milk Commission of the Medical Society of the County of New York has made its annual report which shows that its work has progressed successfully during the past year. The commission has certified to the production of 11,842 quarts of milk daily, produced on twenty-two farms, of which that from seventeen farms is bottled milk produced throughout the year. In addition 2,580 quarts daily from six other farms were inspected. Last year four new farms were added to the certified list. These new farms were in general superior in equipment to the older ones, and the results of the tuberculin tests were in some respects more encouraging. The commission urged on the members of the society an increased interest in certified milk, since it was only by the interest of the medical profession that such a movement could thrive.

Small-Pox at Niagara Falls.—Dr. Herman M. Biggs, New York City, State Commissioner of Health, on January 25 telegraphed to Dr. Edward Clark, Buffalo, in charge of the department campaign against small-pox in Niagara Falls, to have a meeting called by the mayor of the local authorities, manufacturers and business men, at which the following demands of the department, in regard to the epidemic, were to be made: Close all places of public assemblage, including churches, theaters, dance halls, moving-picture theaters and other places of entertainment; close the public schools, or exclude unvaccinated children from attendance; close all factories or exclude unvaccinated employees; close all hotels or require vaccination of employees; enforce a rigid quarantine against all houses containing small-pox cases and all exposed and unvaccinated persons; remove all cases to isolation hospital; enforce strictly the sanitary code of the city. The small-pox situation is constantly improving since the vigorous action of the State Board of Health and the local civil and medical authorities in enforcing vaccination and thorough quarantine. February 2 there were reported 110 cases still under quarantine with few new cases, and vaccination was still going on among schoolchildren and the employees of industrial establishments and business houses. The threatened proclamation by State Health Commissioner Biggs that it would be dangerous to visit Niagara Falls was not issued in view of the improved situation. The health authorities on the Canadian side, however, require that all persons coming from or going to Niagara Falls must have been successfully vaccinated within seven years.

New York City

Hospital Leases Dwellings.—The New York Hospital has extended its control over additional property in its vicinity by leasing two dwellings just opposite the hospital on West Sixteenth Street. Recently it was announced that a block had been purchased further up town as a site for a new building.

Typhus Fever at Quarantine.—A case of typhus fever was discovered on the steamship *Rochambeau* which arrived in New York on January 27, and another case has developed among the steerage passengers on the *Belvidere,* detained at Hoffman's Island for observation; this makes seven cases of typhus met with at this port since January 7.

Diphtheria on Warships.—A short time ago it was noted that diphtheria had appeared on the battleship *Arkansas* and that the officers and men were quarantined at the Brooklyn Navy Yard. Several new cases have been discovered on the *Arkansas* and one has appeared on the *North Dakota.* There are in all more than two thousand men under quarantine and close scrutiny.

Contagious Hospital for Queens.—The Board of Estimate passed a resolution on February 6 authorizing the Board of Health to go on with the work of constructing a hospital for contagious diseases on Haacke farm near Jamaica, L. I. A large number of the residents of Queens objected to this site for the hospital, but the committee appointed to investigate reported that there was no other site available.

Out Practice Alumnae Honor Fellow Worker.—A subscription dinner is to be given by the alumnae of the out practice of the New York Infirmary to Dr. Annie S. Daniel in recognition of her work in the out practice, February 19, at the Hotel McAlpin. The speakers are representatives of Dr. Daniel's varied fields of activity and it is hoped to gather together on this occasion the men and women who have been associated with her work.

Laymen to Aid Health Department.—Dr. Sigismund S. Goldwater, who assumed charge of the office of health commissioner February 2, proposes to have, in addition to the medical advisory board, a committee of laymen to act in conjunction with it, and to advise the department and the commissioner as to plans of action. He also announces his intention of tabulating the tuberculosis cases in the city, many instances of which are unrecognized.

Personal.—Prof. Emil Abderhalden of the University of Halle, Germany, has received a call to lecture at Columbia University. He will begin his lectures next autumn.——Dr. George E. Brewer has been appointed to the chair of surgery at the College of Physicians and Surgeons of Columbia University. This post carries with it the important position of head of the surgical division of the Presbyterian Hospital. ——Dr. Walter B. James has asked to be relieved from membership in the medical faculty of Columbia University. He will retain his professorship and continue to direct research students from time to time.

Physicians' Aid Association Meets.—The Physicians' Mutual Aid Association of New York held its forty-fifth annual meeting recently at the New York Academy of Medicine and elected the following officers: *president,* Dr. W. F. Mittendorf; *vice-presidents,* Drs. W. C. Phillips and J. W. Ingalls; *recording secretary,* Dr. A. Edward Davis; *corresponding secretary,* Dr. W. B. Jennings; *assistant secretary,* Dr. Edward S. Peck; *treasurer,* Dr. Daniel Lewis. The association has a membership of 367, and has paid out $39,000 for 39 deaths. The expenses for each member was $20 during the past year. The club has a reserve and beneficiary fund of $83,000.

Central Council of Public Health Created.—The third conference of the private health agencies of the city interested in some phase of public health work was held in the New York Academy of Medicine on February 4. A plan of organization for the Health Federation of the City of New York was adopted. About 150 private organizations are interested in this federation. The plan includes the establishment of an advisory body to be known as the Central Council of Public Health. The membership of this council is limited to fifteen persons and the following members were announced: Dr. John H. Huddleston, Bailey B. Burritt, Dr. Charles Loomis Dana, Homer Folks, Miss Pauline Goldmary of the Consumer's League, James Perkins, Dr. Edward L. Keyes, Jr., Dr. Philip Vaningen, Miss Lillian D. Wald, Prof. C. E. A. Winslow and E. H. Lewinski-Corwin.

OHIO

Personal.—Dr. Carl A. Hamann has been placed in charge of the surgical department, and Dr. C. B. Carter in charge of the medical department of the Cleveland City Hospital.——Dr. George L. King, Alliance, has been appointed a member of the consulting staff of the Ohio State Blind Commission.——Dr. Isabelle L. Watson, Ashtabula, was operated on in the Ashtabula General Hospital, January 29, and is reported to be doing well.

New Officers.—Stark County Medical Society, at Canton, January 20: president, Dr. Henry C. Eyman, Massillon; secretary-treasurer, Dr. Charles A. LaMont, Canton, (reelected).

Butler County Medical Society, at Hamilton, January 15: president, Dr. Louis H. Frechtling; secretary-treasurer, Dr. Wilmer E. Griffith, both of Hamilton.——Canton Medical Society, January 20: president, Dr. Lewis A. Buchmann; secretary-treasurer, Dr. Grover C. Goudy (reelected).——Salem Physicians' Club, January 29: president, Dr. John S. Gallagher; secretary, Dr. Ludwig F. Derfus.

Scientific Exhibit for State Association Meeting.—In addition to the usual commercial exhibits the Ohio State Board of Health, the Ohio Commission for the Blind and the Ohio Board of Administration are preparing scientific exhibits for the next annual meeting of the Ohio State Medical Association, to be held in Memorial Hall, Columbus, May 5, 6 and 7. The State Board of Health has arranged to show its elaborate traveling public health exhibit in the hall during the convention, presenting in conjunction the usual "health week" program of lectures, mechanical models and moving pictures

Cincinnati

Personal.—Prof. William B. Wherry, who has been confined to his home through serious illness, is now reported as convalescent.——Dr. Arch I. Carson received the appointment of clinical professor of surgery in the College of Medicine, University of Cincinnati.

Officers of Research Society.—The annual election of officers of the Cincinnati Research Society took place February 5. The following physicians were elected: president Dr Oscar Berghausen; vice-president, Dr. E. R. Remelin; secretary, Dr. J. L. Tuechter; executive committee, Dr. H. McE. Knower and Dr. Charles Goosman.

OKLAHOMA

State Board May Revoke Licenses.—The assistant attorney general has ruled that it is not necessary for the State Board of Medical Examiners to go into court for the purpose of revoking licenses for the practice of medicine in the state.

Personal.—Dr. Edward F. Hurlburt, Chandler, was seriously injured in a runaway accident recently.——Dr. J. W. Coleman has been appointed assistant city physician of Muskogee, to care for the indigent colored population of the city.——Dr. William M. Cott, Okmulgee, who was operated on for appendicitis in St. Louis recently, has recovered and returned home.——Dr. Parkey H. Anderson has been appointed Indian physician at Anadarko.——The University of Michigan has conferred on Dr. Edward H. Troy, McAlester, the degree of B.A. in acknowledgment of work done by him since leaving the university.

New Officers.—Ottawa County Medical Society: president, Dr. John C. Jacobs; secretary-treasurer, Dr. Guy P McNaughton, both of Miami.——Seventh Consular District Medical Society, at Muskogee, January 27: president, Dr John E. Bercaw, Okmulgee; secretary-treasurer, Dr. James T. Nichols, Muskogee.——Tillman County Medical Society, at Frederick, January 27: president, Dr. H. L. Roberts; secretary-treasurer, Dr. Lang A. Mitchell, both of Frederick.——Harmon County Medical Society, organized at Hollis: president, Dr. James E. Jones; secretary-treasurer, Dr. Samuel W. Hopkins, both of Hollis.——Jefferson County Medical Society, at Waurika: president, Dr. T. E. Ashinhurst, Waurika; secretary-treasurer, Dr. Ollie E. Clements, Hastings.——Central Medical Association, at Enid, January 21: president, Dr. Dolph D. McHenry, Oklahoma City; secretary-treasurer, Dr. J. Marvin Cooper, Enid (reelected).——Sequoyah Medical Society: president, Dr. James A. Cheek, Hanson; secretary-treasurer, Dr. Stanley B. Jones, Sallisaw.

PENNSYLVANIA

Anniversary Banquet.—At the twenty-ninth anniversary banquet of the Luzerne Medical Society, held at Wilkes-Barre, January 28, the sixty-ninth birthday anniversary of Dr. George W. Guthrie was also celebrated.

Small-Pox in Erie County.—Under date of February 2 an epidemic of small-pox was reported from the town of North East, 18 miles east of Erie. The town has 3,000 inhabitants and ninety cases of small-pox had occurred. A representative of the State Board of Health was sent to take charge of the situation.

Personal.—Dr. Samuel B. Crothers, Chester, has been appointed a member of the board of trustees of the Eastern Pennsylvania Institution for the Feeble-Minded and Epileptic, Spring City.——Dr. David Hollenbeck, Shamokin, is reported to be seriously ill with pneumonia.——Henry W. Pierson, for seven years chief of the division of biological products of the State Health Department and closely identified with the antitoxin division, has tendered his resignation to Commissioner Dixon.

Philadelphia

Personal.—Dr. John K. Mitchell was elected a director of the Poor Richard Inn Club on February 7.——Dr. Charles H. J. Barnett was appointed a district police surgeon on February 7, to take the place of Dr. Nathan Hornstine.——Drs. Jack Pearl and Joseph McIver qualified in the Civil Service Examination as assistant resident physicians in the Bureau of Charities.

Examination of Delinquents.—All children that may be brought before the Probation Department of the new Municipal Court will be put to a scientific test to ascertain their mental and physical conditions. The system has been carefully worked out by Dr. Walter S. Cornell, Chief Medical School Inspector, with the assistance of Judge James E. Gorman and the chief probation officer. The work at the House of Detention has shown that about 5 per cent. of the children brought there are actually feeble-minded and 9 per cent. are backward mentally as to be termed border-line cases. Under the new system the medical staff will have the assistance of the probation officers, the teachers of the House of Detention and of the Psychologic Laboratory of that institution in the collection of information regarding the intelligence of the children's parents, the language spoken at home, the general home conditions, previous schooling of the child, history of truancy and the grade attained in school. With this information, a combined mental and physical examination is made by the chief medical examiner by which the child's intelligence, emotional peculiarities and physical condition are determined and a diagnosis of mentality is made

TENNESSEE

A Poster Form of Health Report.—Gallatin, a small city of 2,400 inhabitants, seems to have a live health officer and local health department. The report of the vital and morbidity statistics and of the general health conditions for 1913 is gotten up in the form of a small poster with an appropriate cartoon. It has the striking headline: "Keeping Tab on the Grim Reaper," and presents in graphic and tabulated form the health status of the city and a comparative statement of health conditions for a number of years. The information is presented in a form that should be of great interest to all the people of Gallatin, and contains a plea by the health officer for the cooperation of all the inhabitants in making the health conditions of the place still better.

GENERAL

Induced Pneumothorax in Tuberculosis.—Dr. Martin F. Sloan, superintendent of the Eudowood Sanatorium, Towson, Md., has been engaged as expert to introduce the treatment of pulmonary tuberculosis by induced pneumothorax at the United States Public Health Service Sanatorium, Fort Stanton, N. Mex. Of the two hundred patients under treatment at the sanatorium, all adult males, thirty have been selected as suitable for treatment by this method.

Bequests and Donations.—The following bequests and donations have recently been announced:

Royal Victoria Hospital, Montreal, $500,000; hospitals of the British Isles, $20,000, by the will of Lord Strathcona and Mount Royal.

St. Francis Hospital, Poughkeepsie, N. Y., for building fund, $2,425.

Mount Sinai Hospital, New York City, one-fourth of the residuary estate of Constant Meyer, amounting to about $18,000.

National Temperance Hospital, Chicago, $1,000; Wesley Hospital, Chicago, $2,500, by the will of Sarah E. Lyons, Rochester, Ill.

Detroit Tuberculosis Sanatorium, $12,000, donation by Mrs. Horace E. Dodge.

Harvard University, the greater part of an estate of $500,000 for medical research and "for the promotion of good citizenship under the Republican government," in memory of the testator's father, by the will of Morill Wyman, Cambridge, Mass.

Public Health Administration of Maryland.—The United States Public Health Service has from time to time, as authorized by Congress, published the results of investigations, and analyses of laws and regulations in respect to the powers and duties of state and local health authorities and laws relating to the control of communicable diseases. In *Public Health Reports*, Jan. 30, 1914, Dr. Carroll Fox of the United States Public Health Service presents an exhaustive study of the laws relating to public health administration in Maryland. The report keeps in view the relations between state and national health laws and regulations, and is valuable not only as pointing out short-comings in the health regulations in this particular state, but in calling attention to matters of duplication between the laws of the state and national health laws. It also affords a basis for study of the health laws of other states by which similar shortcomings and duplications may be determined. The report occupies eighty pages of this number of the *Public Health Reports.*

Congress on Diseases of Occupation.—A committee has been organized for the purpose of inviting the attention of the medical profession and others interested in the prevention of occupational diseases to the Third International Congress on Diseases of Occupation to be held in Vienna in September, 1914. These congresses, begun in 1906, afford an excellent opportunity to scientists, clinicians and industrial experts to present the results of their research and observations before an international body specially interested in the subject. Among the topics which will be considered at the coming congress are: the physiology and pathology of fatigue; work in hot and damp air; occupational anthrax; pneumoconiosis: injuries caused by electricity; industrial poisons; injuries of hearing caused by industrial pursuits, etc. For membership fees, mail postal money order for $5 to the general secretary of the congress, Dr. Ludwig Teleky, No. 23, Türkenstrasse IX, Vienna, Austria. For further information, address Dr. Alice Hamilton, Secretary, Hull House, Chicago, or Dr. George M. Kober, Vice-Chairman, 1819 Q Street, N.-W., Washington, D. C.

FOREIGN

Deaths in the Profession Abroad.—The cable reports the death of Dr. Karl Voelckers, the well-known ophthalmologist, aged 77, at Kiel, Germany, where he served as professor of ophthalmology from 1866 until recently. He has published numerous works on his specialty, especially on the mechanism of accommodation.——G. Cesari, professor of materia medica at the University of Modena, Italy.

CANADA

Hospital Report.—At the annual meeting of the Verdun Protestant Hospital, Verdun, Quebec, a deficit of $2,526 was reported. The total receipts during 1913 were $159,938, while the expenditures were $162,465. The reason for the deficit is partly the high cost of living and the insufficient per capita allowance by the provincial government of $142. In his twenty-fourth annual report the medical superintendent, Dr. J. W. Thomas Burgess, said that during the year there had been 477 men and 433 women under treatment, a total of 910. There were 247 admissions and of the 151 discharged 74 had recovered, 45 improved and 32 unimproved. There were 92 deaths, leaving in residence at the end of the year 665 patients. There were only eight voluntary admissions. The hospital is for the Protestant insane of the province of Quebec.

Handsome Sanitarium Donation.—Mr. W. J. Gage, Toronto, has donated $100,000 to the National Sanitarium Association. His total gifts to this cause now amount to over a quarter million dollars. The amount is to be added to the King Edward Memorial Fund of $1,000,000 for consumptives, toward which the city of Toronto subscribed $200,000. The city's grant rebuilt the Weston Sanatorium which was destroyed by fire in 1910. Mr. Gage's latest contribution will be used to maintain needy patients in Muskoka. Mr. Gage is practically the founder of the sanatorium movement in Canada. There have been over 7,000 patients cared for by the National Sanitarium Association. At the present time there are about 470 patients in the Muskoka and Weston institutions, most of them being free patients. The plant and equipment are to-day valued at $500,000, and it costs $225,000 annually for maintenance and upkeep.

Dr. Minot Lectures at McGill.—Dr. Charles Sedgewick Minot, professor of anatomy and embryology at Harvard University, recently delivered a lecture to the medical students of McGill University, Montreal. The lecture took the form of a reply to the toast to his health at the thirty-second annual banquet of the faculty and students. Dr. Minot declared that medicine made the highest demands on the mind and character of perhaps any profession, and the fundamental thing that leads to success was what the speaker called a god-like apprehension—the power of understanding things as they really are. The toast to Alma Mater was responded to by President Peterson. Prof. George E. Armstrong replied to the toast to the faculty of medicine, while Prof. John G. Adami gave the toast to the graduating class, emphasizing the value of specializing and urged the students to take up some hobby to which they could turn as a relief from dealing with disease.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Jan. 23, 1914.

Personal

At its last session the Académie des Sciences elected Dr. Charles Richet, professor of physiology at the Faculté de médecine de Paris, a member of the section of medicine and surgery to replace the late Dr. Lucas-Championnière. It will be remembered that a Nobel prize was recently awarded Dr. Charles Richet (THE JOURNAL, Nov. 22, 1913, p. 1915).

Institutes of Child Hygiene

Eleven institutes of child hygiene have been opened in the various services of obstetrics and pediatrics in Paris. Instruction in child hygiene will be placed within the reach of all Parisian mothers. Each year, the head of each service in which there is an institute of child hygiene will make a report to the general administration of the public charities on the number of consultations, the number of children examined, the number of pupils following courses, the quantity of milk distributed, etc.

Boric Acid in Foodstuffs

The addition of boric acid to foodstuffs is forbidden by law. Two years ago, when fruit was scarce, large importations of dried and preserved fruits were made from Canada. French merchants declared that these fruits contained boric acid. Qualitative analysis indicated the presence of this antiseptic, and the entrance of Canadian fruit into France was accordingly forbidden. At the protest of Canada an investigation was made. M. Gabriel Bertrand, chief of service at the Pasteur Institute and professor at the Sorbonne, was commissioned to make a quantitative analysis capable of determining the presence of extremely small quantities of boric acid. He, together with M. Agulhon, has just presented to the Académie des Sciences a note on this subject. Since the constant presence of boron in almost all living cells has been unknown hitherto, it has been generally believed that the boric acid found in the ashes of animal or vegetable foodstuffs indicated its artificial introduction as an antiseptic. A mere qualitative analysis is no longer sufficient, for boron or boric acid is found everywhere. The method devised by Bertrand permits a sufficiently close analysis to avoid the confusion of the boric acid contained normally in the ashes of foodstuffs with that which may have been introduced as an antiseptic. In a kilogram of dried fruit, Bertrand and Agulhon found in apricot pulp about 112 mg., in strawberries 56 mg., in cherries 112 mg., in black raisins 228 mg., and in English pears 28 mg. In almost all vegetables, such as carrots, gherkins, Scottish beans, dried onions, turnips, are found quantities of boric acid. from 56 to 112 mg. per dry kilogram.

Antityphoid Vaccination in the Schools

The municipal council of Paris has just requested the administration to collect the number of typhoid cases in each quarter and to publish a table, showing the figures with those of the corresponding school population, to furnish a basis for studying the means of supplying serum to the physicians of the schools most affected.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Jan. 24, 1914.

Personal

The noted biologist, August Weismann, celebrated his eightieth birthday, January 17.

The Insurance Conflict

The conflict in Königsberg with the local insurance society has been settled by the intervention of the government. On the average $1.80 (7.20 marks) per capita and 25 cents (1 mark) for extra services has been granted to physicians as well as, what is a matter of chief importance, a free choice of physician to the full extent that has prevailed heretofore. The position taken by the medical faculty of the university contributed materially to induce the insurance society to make concessions. The insurance societies of the consulting staff of the Ohio State Blind Commission. ——Dr. Mabelle L. Watson, Ashtabula, was operated on in the Ashtabula General Hospital, January 29, and is reported to be doing well.

New Officers.—Stark County Medical Society, at Canton, January 20: president, Dr. Henry C. Eyman, Massillon; secretary-treasurer, Dr. Charles A. LaMont, Canton, (reelected). ——Butler County Medical Society, at Hamilton, January 15: president, Dr. Louis H. Frechtling; secretary-treasurer, Dr. Wilmer E. Griffith, both of Hamilton.——Canton Medical Society, January 30: president, Dr. Lewis A. Buchmann; secretary-treasurer, Dr. Grover C. Goudy (reelected).——Salem Physicians' Club, January 29: president, Dr. John S. Gallagher; secretary, Dr. Ludwig F. Derfus.

Scientific Exhibit for State Association Meeting.—In addition to the usual commercial exhibits the Ohio State Board of Health, the Ohio Commission for the Blind and the Ohio Board of Administration are preparing scientific exhibits for the next annual meeting of the Ohio State Medical Association, to be held in Memorial Hall, Columbus, May 5, 6 and 7. The State Board of Health has arranged to show its elaborate traveling public health exhibit in the hall during the convention, presenting in conjunction the usual "health week" program of lectures, mechanical models and moving pictures.

Cincinnati

Personal.—Prof. William B. Wherry, who has been confined to his home through serious illness, is now reported as convalescent.——Dr. Arch I. Carson received the appointment of clinical professor of surgery in the College of Medicine, University of Cincinnati.

Detroit Tuberculosis [illegible], donation by Mrs. Horace E. Dodge.

Harvard University, the greater part of an estate of $500,000 for medical research and "for the promotion of good citizenship under the Republican government," in memory of the testator's father, by the will of Morill Wyman, Cambridge, Mass.

Public Health Administration of Maryland.—The United States Public Health Service has from time to time, as authorized by Congress, published the results of investigations, and analyses of laws and regulations in respect to the powers and duties of state and local health authorities, and laws relating to the control of communicable diseases. In *Public Health Reports*, Jan. 30, 1914, Dr. Carroll Fox of the United States Public Health Service presents an exhaustive study of the laws relating to public health administration in Maryland. The report keeps in view the relations between state and national health laws and regulations, and is valuable not only as pointing out short-comings in the health regulations in this particular state, but in calling attention to matters of duplication between the laws of the state and national health laws. It also affords a basis for study of the health laws of other states by which similar shortcomings and duplications may be determined. The report occupies eighty pages of this number of the *Public Health Reports.*

Congress on Diseases of Occupation.—A committee has been organized for the purpose of inviting the attention of the medical profession and others interested in the prevention of occupational diseases to the Third International Congress on Diseases of Occupation to be held in Vienna in September, 1914. These congresses, begun in 1906, afford an excellent opportunity to scientists, clinicians and industrial experts to present the results of their research and observations before an international body specially interested in the subject. Among the topics which will be considered at the coming congress are: the physiology and pathology of fatigue; work in hot and damp air; occupational anthrax; pneumoconiosis; injuries caused by electricity; industrial poisons; injuries of hearing caused by industrial pursuits, etc. For membership fees, mail postal money order for $5 to the general secretary of the congress, Dr. Ludwig Teleky, No. 23, Türkenstrasse IX, Vienna, Austria. For further information, address Dr. Alice Hamilton, Secretary, Hull House, Chicago, or Dr. George M. Kober, Vice-Chairman, 1819 Q Street, N.-W., Washington, D. C.

FOREIGN

Deaths in the Profession Abroad.—The cable reports the death of Dr. Karl Voelckers, the well-known ophthalmologist, aged 77, at Kiel, Germany, where he served as professor of ophthalmology from 1866 until recently. He has published numerous works on his specialty, especially on the mechanism of accommodation.——G. Cesari, professor of materia medica at the University of Modena, Italy.

CANADA

Hospital Report.—At the annual meeting of the Verdun Protestant Hospital, Verdun, Quebec, a deficit of $2,526 was reported. The total receipts during 1913 were $159,938, while the expenditures were $162,465. The reason for the deficit is partly the high cost of living and the insufficient per capita allowance by the provincial government of $142. In his twenty-fourth annual report the medical superintendent, Dr. J. W. Thomas Burgess, said that during the year there had been 477 men and 433 women under treatment, a total of 910. There were 247 admissions and of the 151 discharged 74 had recovered, 45 improved and 32 unimproved. There were 92 deaths, leaving in residence at the end of the year 665 patients. There were only eight voluntary admissions. The hospital is for the Protestant insane of the province of Quebec.

Handsome Sanitarium Donation.—Mr. W. J. Gage, Toronto, has donated $100,000 to the National Sanitarium Association. His total gifts to this cause now amount to over a quarter million dollars. The amount is to be added to the King Edward Memorial Fund of $1,000,000 for consumptives, toward which the city of Toronto subscribed $200,000. The city's grant rebuilt the Weston Sanatorium which was destroyed by fire in 1910. Mr. Gage's latest contribution will be used to maintain needy patients in Muskoka. Mr. Gage is practically the founder of the sanatorium movement in Canada. There have been over 7,000 patients cared for by the National Sanitarium Association. At the present time there are about 470 patients in the Muskoka and Weston institutions, most of them being free patients. The plant and equipment are to-day valued at $500,000, and it costs $225,000 annually for maintenance and upkeep.

Dr. Minot Lectures at McGill.—Dr. Charles Sedgewick Minot, professor of anatomy and embryology at Harvard University, recently delivered a lecture to the medical students of McGill University, Montreal. The lecture took the form of a reply to the toast to his health at the thirty-second annual banquet of the faculty and students. Dr. Minot declared that medicine made the highest demands on the mind and character of perhaps any profession, and the fundamental thing that leads to success was what the speaker called a god-like apprehension—the power of understanding things as they really are. The toast to Alma Mater was responded to by President Peterson. Prof. George E. Armstrong replied to the toast to the faculty of medicine, while Prof. John G. Adami gave the toast to the graduating class, emphasizing the value of specializing and urged the students to take up some hobby to which they could turn as a relief from dealing with disease.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Jan. 23, 1914.

Personal

At its last session the Académie des Sciences elected Dr. Charles Richet, professor of physiology at the Faculté de médecine de Paris, a member of the section of medicine and surgery to replace the late Dr. Lucas-Championnière. It will be remembered that a Nobel prize was recently awarded Dr. Charles Richet (The Journal, Nov. 22, 1913, p. 1915).

Institutes of Child Hygiene

Eleven institutes of child hygiene have been opened in the various services of obstetrics and pediatrics in Paris. Instruction in child hygiene will be placed within the reach of all Parisian mothers. Each year, the head of each service in which there is an institute of child hygiene will make a report to the general administration of the public charities on the number of consultations, the number of children examined, the number of pupils following courses, the quantity of milk distributed, etc.

Boric Acid in Foodstuffs

The addition of boric acid to foodstuffs is forbidden by law. Two years ago, when fruit was scarce, large importations of dried and preserved fruits were made from Canada. French merchants declared that these fruits contained boric acid. Qualitative analysis indicated the presence of this antiseptic, and the entrance of Canadian fruit into France was accordingly forbidden. At the protest of Canada an investigation was made. M. Gabriel Bertrand, chief of service at the Pasteur Institute and professor at the Sorbonne, was commissioned to make a quantitative analysis capable of determining the presence of extremely small quantities of boric acid. He, together with M. Agulhon, has just presented to the Académie des Sciences a note on this subject. Since the constant presence of boron in almost all living cells has been unknown hitherto, it has been generally believed that the boric acid found in the ashes of animal or vegetable foodstuffs indicated its artificial introduction as an antiseptic. A mere qualitative analysis is no longer sufficient, for boron or boric acid is found everywhere. The method devised by Bertrand permits a sufficiently close analysis to avoid the confusion of the boric acid contained normally in the ashes of foodstuffs with that which may have been introduced as an antiseptic. In a kilogram of dried fruit, Bertrand and Agulhon found in apricot pulp about 112 mg., in strawberries 56 mg., in cherries 112 mg., in black raisins 228 mg., and in English pears 28 mg. In almost all vegetables, such as carrots, gherkins, Scottish beans, dried onions, turnips, are found quantities of boric acid, from 56 to 112 mg. per dry kilogram.

Antityphoid Vaccination in the Schools

The municipal council of Paris has just requested the administration to collect the number of typhoid cases in each quarter and to publish a table, showing the figures with those of the corresponding school population, to furnish a basis for studying the means of supplying serum to the physicians of the schools most affected.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Jan. 24, 1914.

Personal

The noted biologist, August Weismann, celebrated his eightieth birthday, January 17.

The Insurance Conflict

The conflict in Königsberg with the local insurance society has been settled by the intervention of the government. On the average $1.80 (7.20 marks) per capita and 25 cents (1 mark) for extra services has been granted to physicians as well as, what is a matter of chief importance, a free choice of physician to the full extent that has prevailed heretofore. The position taken by the medical faculty of the university contributed materially to induce the insurance society to make concessions. The insurance societies had requested that their members should be treated in the clinics, but the directors of the university clinics and policlinics refused to treat members of the Krankenkassen except in case of imminent danger.

The conflict still continues at the chief remaining foci of disturbance, Brunswick, Elbing and especially Breslau.

Winter Mountain-Climbing

The continually growing disposition to visit the mountains even in winter for the treatment of nervous diseases particularly, has been enhanced by an investigation, a report of which is briefly given by the renowned Berlin physiologist, Professor Zuntz, in the *Zeitschrift für Balneologie.* Zuntz took occasion in the course of the ascent of the highest mountain in the Harz range, the Brocken, by a large party in winter, to carry out some investigations on the effects of mountain-climbing. The thirty-two participants varied in age from 32 to 65 years. A heavy snow-storm considerably increased the exertions connected with the ascent. Three days afterward Zuntz sent to all of these men (who were themselves physicians and hence accustomed to accurate observations) question-blanks in which to record their own observations during and after the expedition. For the interpretation of the reports three age classes were distinguished, namely, those in the fourth, fifth and sixth decades of life. The youngest group was represented by eight men, who for the most part had had insufficient sleep during the previous days and had indulged more freely in alcohol than usual. In spite of this, six of them regarded the ascent as easy and even the two others who found the exertion severe observed no bad aftereffects, although in one, shortly before reaching the top, a fainting-spell occurred. The sixteen men in the fifties made still more favorable reports, probably because they had taken better care of themselves in the previous days. Only two considered the ascent difficult, while the majority noted expressly an increase of vigor after the march. Five of the participants were in the sixties, and those accomplished the ascent best who had been trained for it by gymnastic and Alpine exercise. Zuntz himself was the oldest of the mountain-climbers, being 65, and he suffered a light febrile attack after the undertaking because he had to take a rapid journey to Berlin in his wet clothing. He concludes that these experiences afford striking evidence in favor of the value of the mountain climate in winter. The greatest demands were made on the heat-regulating apparatus of the body, and yet the result in the majority of the participants, even though they were not accustomed to such exertion, was entirely advantageous and showed itself in sound sleep and a feeling of refreshment.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Jan. 10, 1914.

Conflict between Practitioners and Clubs Settled

As mentioned in my previous letter (The Journal, Dec. 27, 1913) the conflict between the organized profession and the Krankenkassen has been in its last stage for several weeks, when it was abruptly settled satisfactorily to the doctors. By intervention of the government, peace was made on the following terms: The clubs—in this country these clubs are compulsory institutions of certain groups of persons earning wages, or otherwise occupied and employed by a person or firm, not by a corporation—have to agree to reappoint all those doctors who have been dismissed or have given notice of resignation within the last year, if these persons wish to accept the post again. Furthermore, two hundred new appointments have to be made within two years. (All these stipulations affect the whole of Lower Austria, with about two and one-half million of inhabitants, and about sixteen hundred doctors.) The payment is calculated per capita in clubs with more than one thousand members, or for a fixed sum, in clubs with fewer members. Each contract between a Krankenkasse and a doctor must be controlled by the medical council of the district; extra medical work (operations, midwifery) to be paid for extra; four weeks' paid leave every year, but the doctor must find a substitute at his own expense during this time. Great difficulties arose in settling the question of dealing with those "blacklegs" who had accepted medical appointments boycotted by the organization during the conflict. The profession demanded the dismissal of these men who had behaved so unethically. But the clubs did not give in. The terms of peace provide that these men may remain, but the posts to which they were appointed will be returned to their previous holders; and the clubs have now to pay not only the regular fees for the appointed old doctors, but also the very heavy "strike fees" of the "blacklegs." Naturally, the clubs will attempt to get rid of these latter men at the very earliest opportunity, and thus the object of the profession will be attained, although a little later, and the punishment for "blacklegs," too. This first significant victory has shown in this country that our profession has ceased to be the object of prey, as it was for a number of years; and the consternation of other unions of clubs is evident by the fact that in Vienna and elsewhere a "voluntary" rectification, i. e., raise of the scale of fees has been offered to the doctors by various Krankenkassen. Meanwhile, the idea of "voluntary choice of doctors for insured members" (*freie Aerztewahl*) is making good headway among our population, and already the members of the pharmaceutical profession have taken it up too.

A New Physiologic Institute

By the generous bequest of 1,500,000 kronen ($300,000) under the will of the late Professor Leegen, a former member of the Vienna medical faculty, the Academy of Sciences of Vienna has obtained means to erect a special institute for physiology. The idea is to devote the institute to scientific research solely; no beginners will be admitted, and the men working there will be appointed as whole-time officers, who may *not* devote their time to any other office (as teachers in universities or hospitals). Furthermore, the academy has obtained also the Vienna Biologic Institute, together with a handsome sum to keep it going, from its founders and present owners. From this institute emanated the sensational biologic discoveries by Drs. Kammerer and Pribram and now, in connection with the above-mentioned "Leegen institute," experimental physiology on a large scale, for purely scientific purposes will be possible in this city, apart from the research going on in the university institute devoted chiefly to the interests of students and for teaching.

The Thirtieth Anniversary of the Death of Gregor Mendel

A few days ago, the Mendelian Society celebrated the thirtieth anniversary of Mendel's death by opening up a new institute devoted to the research of the Mendelian laws of heredity. A modest statue of the scientist was unveiled some time ago in Brünn, where he had spent the latter part of his life and conducted his researches as abbé at the monastery.

Reform in the Medical Service of the Army

The recent discussion in the Austrian Parliament of the budget of the ministry of war proves that our authorities pay more attention now to the requirements of the army medical department. At present we have over 400 fully trained surgeons with at least one year's service in surgical clinics; and no longer than ten years ago, this was suggested as desirable. Many of them have also had several terms in clinics for ear, eye, nose, throat and skin departments. Promotion has been so arranged that after fifteen to twenty years of service, the medical officer of the army will attain the rank of staff-surgeon. At the same time a number of scholarships for different university and hospital clinics have been added to those already in existence, and have been substantially financed. It is the endeavor of the leading authorities to spend 3 per cent. of the grand total of the expenditure on the army for medical purposes, as against 2 per cent. hitherto. The number of male attendants in the sick wards will be augmented, so that sixteen to twenty beds will have the services of one man, while the outfit of the laboratories and the therapeutic departments will be brought up to date, including Roentgen-ray apparatus, filters, sterilization plants, ambulance cars, and last but not least, the number of army doctors will be increased and their position made equal to that of the officers of the rank and file.

Decrease in the Number of Foreign Doctors in Vienna

During the last few months, the number of foreign doctors who used to come here for purposes of study, has decreased very markedly. The drop has affected chiefly the British and Americans, who have left for the holidays to see their families, while newcomers have not arrived, as was formerly the custom. On the other hand, there is an increase in arrivals from Russia and the northern countries (Sweden, Norway, Denmark). Nevertheless, the opportunities for teaching and learning have increased within the last year or two by the finishing of the new clinics and the erection of two new special hospitals. For the month of March, at any rate, a large number of doctors have booked beforehand in several private ambulance departments, so that we look forward to a very busy spring.

Marriages

Frank Joseph Wochos, M.D., Kewaunee, Wis., to Miss Nunie Kustermann of Green Bay, Wis., at Chicago, February 4.

Merrill Kirk Lindsay, M.D., Topeka, Kan., to Mrs. William Drecksel of Leavenworth, Kan., at Topeka, January 25.

Frederick A. Stevens, M.D., Lake Elmo, Minn., to Miss Gertrude Londigan of Stillwater, Minn., January 24.

Thomas A. Woodruff, M.D., to Mrs. Carrie M. Ogden, both of Chicago, at New London, Conn., February 7.

John F. O'Brien, M.D., Taunton, Mass., to Miss Rose Teresa Dillon of Fall River, Mass., January 7.

Peter Aloyes Eck, M.D., to Miss Lillian D. Birkle, both of St. Louis, at Clayton, Mo., January 19.

George Frederick Dick, M.D., Chicago, to Gladys Rowena Henry, M.D., of Evanston, January 27.

Charles Osgood, M.D., New York City, to Miss Loretto Coleman of Portland, Me., July, 1913.

Claude Melvin Campbell, M.D., to Miss Rose F. Beihoffer, both of Starbuck, Minn., January 3.

Melvin Josiah McKay, M.D., to Miss Florine Losee, both of Lake City, Iowa, January 21.

John F. Christiansen, M.D., Manville, Wyo., to Miss Louise Cook of Illinois, recently.

Frank Edgar Simmons, M.D. to Miss Helen Sloan, both of Canajoharie, N. Y., recently.

Deaths

William Green Ewing, M.D. Vanderbilt University, Nashville, Tenn., 1877; for several years chairman of the Board of Health of Nashville; formerly professor of materia medica and dean of the medical department of the University of Nashville and Vanderbilt University, and president of the faculty of the Medical Department of the University of Tennessee; died at his home in Nashville, January 14, from heart disease, aged 65.

John Avery, M.D. Cleveland University of Medicine and Surgery, 1850; assistant surgeon of the Twenty-First Michigan Volunteer Infantry and brigade surgeon during the Civil War, and since its close a practitioner of Greenville, Mich.; a member of the Fifty-Third and Fifty-Fourth Congresses; for twelve years a member of the State Board of Health; died at his home, January 21, from cerebral hemorrhage, aged 89.

William Howard Ulsh, M.D. University of Pennsylvania, Philadelphia, 1893; assistant surgeon U. S. Navy (retired), with previous service in the line and in the Spanish-American War; aged 42; retired in 1902 for incapacity resulting from an incident of service, and since his retirement a resident of Selinsgrove, Pa.; was instantly killed, January 21, near Kramer, by being crushed under his overturned motor car.

Lewis Y. Grubbs, M.D. Medical College of Ohio, Cincinnati, 1871; a Fellow of the American Medical Association and a pioneer practitioner of Kansas; a veteran of the Civil War; one of the organizers and president of the medical staff of the Jane C. Stormont Hospital, Topeka; died at his home in that city, January 25, from cerebral hemorrhage, aged 72.

Roger De Montluzin, M.D. Tulane University, New Orleans, 1886; surgeon-general of Mississippi on the staff of Governor Foster; vice-president of the Merchants' Bank of Bay St. Louis, and formerly president of the local board of health; for many years disabled by reason of paralysis; died at his home in Bay St. Louis, January 16, aged 51.

Joseph Silas Baer, M.D. Jefferson Medical College, 1888; a Fellow of the American Medical Association; until 1912 a resident of Camden, N. J., gynecologist to Cooper Hospital and once president of the Camden County Medical Society; died at his home in South Pasadena, Cal., January 19, aged 59.

W. A. H. Campbell, M.D. Louisville (Ky.) Medical College, 1888; a member of the Kentucky State Medical Association; of Pikeville; died January 2, from injuries received in falling from his horse over a steep embankment.

John Graham Paschall, M.D. Baylor University, Dallas, Tex., 1906; a member of the State Medical Association of Texas; of Dallas; died in a hospital in San Antonio, January 19, after a surgical operation, aged 33.

James H. P. Baker, M.D., Rush Medical College, 1868; a member and once vice-president of the Missouri State Medical Association; local surgeon at Salisbury for the Wabash System, and formerly president of the Wabash Railway Surgeons' Association; died at his home in Salisbury, Dec. 20, 1913, aged 76.

David Henry Patton, M.D. Northwestern University Medical School, Chicago, 1867; a member of the Oklahoma State Medical Association; for several years a resident of Oklahoma City and Woodward; died at the home of his daughter in Otterbein, Ind., January 17, from heart disease, aged 76.

William L. Smith, M.D. Kentucky School of Medicine, Louisville, 1893; a member of the Missouri State Medical Association; for several terms coroner of Christian County; a practitioner of Sparta until 1908; died at his home in Springfield, January 20, from pneumonia, aged 47.

Pliny Henry Perkins, M.D. Rush Medical College, 1897; a Fellow of the American Medical Association; local surgeon of the Colorado Midland Railway, at Colorado Springs; attending surgeon to St. Francis' Hospital; died in that institution, January 16, from pneumonia, aged 40.

Charles M. Lyon (license, Illinois, 1877); a member of the Illinois State Medical Society; a veteran of the Civil War; for three terms a member of the State Legislature; owner and editor of the *Hamilton County Leader;* died at his home in McLeansboro, January 25, aged 70.

Thomas Richard Garlington, M.D. Jefferson Medical College, 1890; a member of the Medical Association of Georgia; medical director of the State Mutual Life Insurance Company; a resident of Rome; died at the home of his father-in-law near Atlanta, January 21, aged 54.

Augustus Esenwein, M.D. Philadelphia College of Medicine, about 1856; assistant paymaster in the Navy during the Civil War; for many years a practitioner of Reading; died at the home of his son in Philadelphia, January 10, from senile debility, aged 79.

Frank Joseph Labie, M. D. Rush Medical College, 1894; a member of the Illinois State Medical Society, and for twenty years resident surgeon at the St. Mary of Nazareth Hospital, Chicago; died in that institution, February 8, from pneumonia, aged 48.

William Webb, M.D. Jefferson Medical College, 1849; a member of the Missouri State Medical Association and a surgeon in the Confederate service throughout the Civil War; died at his home in St. Louis, January 21, from senile debility, aged 80.

George Oliver Barnes, M.D., Miami Medical College, Cincinnati, 1876; a member of the Indiana State Medical Association, and for many years a member of the Jackson County Board of Health; died at his home in Seymour, January 16, aged 75.

Charles E. Robson, M.D. Kentucky School of Medicine, Louisville, 1903; aged 36; a Fellow of the American Medical Association and health officer of Tenino, Wash., was shot and killed January 13, in Tenino by the husband of a patient.

Wesley Park, M.D. Northwestern University Medical School, Chicago, 1867; Jefferson Medical College, 1873; formerly president of the Park Bank at Fieldon, Ill.; died at his home in Grafton, Ill., January 18, aged 80.

Godfrey R. Bourke, L.R.C.S., Ireland, 1869; a practitioner of New York City, and a member of the Medical Society of the State of New York; died at his summer home in Sayville, L. I., January 23, from pneumonia.

John Augustus Stratton, M.D. University of Michigan, Ann Arbor, 1882; manager of the Stratton Sanitarium, Newman, Cal.; died at his home, January 15, from disease of the liver, aged 56.

William F. Osborn, M.D. Rush Medical College, 1860; for one term a member of the Kansas Legislature from Douglas County; died at his home in Baldwin, January 21, aged 83.

George W. Davis, M.D. Howard University, Washington, D. C., 1907; anesthetist to the Freedmen's Hospital, Washington; died at his home in that city, January 14, aged 30.

Matthew Winfield Smith, M.D. Bellevue Hospital Medical College, 1873; died at his home in Brooklyn, N. Y., January 9, aged 60.

John Albion Soule (license, Massachusetts, years of practice, 1894) died at his home in Hyde Park, Dec. 10, 1913, aged 72.

William J. Hodges, M.D. Atlanta (Ga.) Medical College, 1871; died at his home in Atlanta, January 7, aged 65.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

DR. BURTON TAKES THE JOURNAL TO TASK

To the Editor:—I read with much interest the article in your excellent journal published December 13, on the action of vaccines and serums, and I wish to ask in good faith a question. The article seems to be directed toward such firms as Parke, Davis and Co. and the Sherman Vaccine Laboratory of this city and it aims to discredit their work and discourage the use of mixed vaccines and Phylacogens. In the same number of your journal you are carrying extensive advertisements from both of these companies and we, as physicians, take this as a criterion that you sanction their use.

We look to The Journal to guide us through ethical channels of practice, and we believe hat if an advertisement is good enough to be printed in The Journal, the products thus advertised are good enough for us to use.

I am voicing the sentiments of a number of physicians I have spoken to about this, and I have no connection whatever with either of the above named firms, although they are both located in Detroit. My question is, then, if you discredit the use of their preparations, why do you advertise them in your own paper? C. H. Burton, M.D., Detroit, Mich.

The article referred to by Dr. Burton appearing in The Journal, Dec. 13, 1913, was a paper on "The Scientific Basis for Vaccine Therapy," by Richard M. Pearce, M.D., of Philadelphia. The Journal does not hold itself sponsor for the views expressed by its contributors, although in the present instance Dr. Pearce's paper reflects the attitude of The Journal on the subject with which it deals.

Advertisements of proprietary remedies are accepted by The Journal only after the products have been investigated by the Council on Pharmacy and Chemistry and accepted for inclusion in New and Nonofficial Remedies. The Phylacogens have never been accepted and have never been advertised in The Journal, although The Journal has at various times criticized these products. Certain of the mixed vaccines were accepted for New and Nonofficial Remedies, and such products have been advertised in The Journal. Last year, after consulting various authorities, the Council decided to apply Rule 10 (which bars unscientific, shotgun mixtures) to vaccine preparations. Under the Council's rules, it was obliged to retain for a period those mixed vaccines which had already been accepted. It decided, however, to accept no further mixtures of this kind. New and Nonofficial Remedies, 1913, explains the Council's actions in this particular thus:

> "Of recent years prophylaxis and therapy by bacterial vaccines have been widely employed. While the subject was still in the experimental stage, mixtures of vaccine, so-called 'mixed' vaccines, were admitted to N. N. R. by the Council. With increasing experience, however, it has been found inadvisable to continue this form of recognition. Those at present included will be dropped at the expiration of three years from the time of their admission and none will be admitted or retained unless justification for their inclusion can be found."

We are glad to learn that Dr. Burton has such a high opinion of The Journal. He will doubtless find much interest in the issues of May 18, 1912, page 1517, and Oct. 12, 1912, page 1391. There, our readers will remember, were discussed Dr. Burton's exploits, first as an associate of the notorious "cancer cure" fakers, "Drs. Mixer," later in exploiting a "cure" for locomotor ataxia. A physician who had read The Journal's exposé called Burton's attention to it. Burton replied that he had intended suing The Journal for slander, "but on looking them up I found that they are not worth anything, so a judgment would do me no good."[1] In view of the foregoing, it gives us pleasure to learn that Dr. Burton is constrained to "look to The Journal to guide us through ethical channels of practice"!

PYO-ATOXIN

"*To the Editor:*—I am sending you a sample of a proprietary preparation that for the past two or three years has been largely retailed in the South and Southwest as a new combination that liberates larger amounts of formaldehyd, etc., in the genito-urinary tract than any known agent, that it is a methylene-formate, entirely new, etc.

"I asked the representative why he had not submitted a specimen to the Council, and his reply was that like Wyeth and others they did not get a fair report, or something to this effect. My reasons for trying to find the truth for their claims is that quite a number of general practitioners have asked me regarding this Pyo-Atoxin.

"W. P. Dey, M.D., Jacksonville, Fla."

Dr. Dey sent with the foregoing letter a box of Pyo-Atoxin which bore this label:

Pyo-Atoxin
Reg. in U S. Pat. Office
(Capsules)
(Pheno-Methylene-Formate)
"Hurley"
An Antitoxic Agent Indicated in
Gonorrhoea, Cystitis, Pyelitis and
Bacteriuric Conditions.
DOSE: One capsule four to six times daily,
Followed by large glass of water.
Guaranteed by
H. O. Hurley,
Manufacturing Pharmacist,
Louisville, Ky.
Under the Food and Drugs Act, June 30, 1906
Serial No. 1710.

The pseudoscientific synonym "pheno-methylene-formate" carries the idea that Pyo-Atoxin is a definite chemical substance. It is unnecessary to say that the term "pheno-methylene-formate" is a meaningless one and its use reminds one of those preparations exploited seven or eight years ago before the Council began to expose these mixtures masquerading as definite chemical compounds.

The chemical laboratory was asked to investigate this preparation and the following is a report of the chemists:

"The box contained thirty gelatin capsules coated with some black substance giving them the appearance of some of the popular gonorrhea nostrums. When the capsules were opened they were found to contain a powder—about 0.35 gm. or 5 grains per capsule—composed of large white or colorless crystals mixed with a smaller amount of a fine dark powder. The crystals when separated out and dissolved yielded the characteristic tests for hexamethylenamin. A solution of the entire capsule content was deep blue and responded to the U. S. P. tests for methylene blue.

"As a result of these and other tests it was concluded that Pyo-Atoxin consisted essentially of two pharmacopeial drugs—hexamethylenamin and methylene blue. A quantitative determination of the constituents was considered unnecessary. From its general appearance and properties, however, the hexamethylenamin probably constitutes approximately from 60 to 80 per cent. of the preparation."

It thus appears that the capsules contain a mixture consisting essentially of two well-known official substances, the value and particularly the limitations of which should be known by physicians by this time. This nostrum is simply another example of how physicians are being humbugged.

CLEAN ADVERTISING

It is individual effort that counts for most in every movement for better things—socially, economically or politically. Realizing this, The Journal repeatedly urges physicians who write regarding various fraudulent advertisements to enter their individual, personal protest against the continuation of such advertisements.

Within the past few months The Journal has had brought to its attention a good example of what may be accomplished by personal effort in cleaning up the advertising pages of a fraternal publication. The *Royal Neighbor*, official organ of a fraternal organization, until comparatively recently, carried numerous fraudulent medical advertisements. Fake liquor cures, rheumatism cures, tapeworm expellers, *tobacco-*

---

[1] Burton's activities will be found described in "Nostrums and Quackery," second edition, page 689.

habit cures, asthma and hay-fever cures, epilepsy cures, etc., disgraced its advertising pages. These called forth protests from Dr. E. A. Hall, Henry, Ill., who addressed letters to the official physicians of the fraternal order that the *Royal Neighbor* represents, objecting to such advertisements. These letters in turn reached the advertising manager, and it was not long before the board of managers took the matter up for consideration and decided to eliminate this class of advertising from their official organ. By December, 1913, the *Royal Neighbor* came to its readers clean. There is no doubt that the same results can be duplicated in similar cases. Whether they are will depend on the amount of active work done by individuals interested in the question of clean advertising.

PIORKOWSKI LABORATORIES NOT LICENSED

Through the Jan. 30, 1914, number of *Public Health Reports*, the United States Public Health Service announces that statements which seem to emanate from the so-called Piorkowski laboratories in various parts of the country, to the effect that these laboratories have been licensed by the Public Health Service, are incorrect. The article states that after inspection of the Piorkowski Laboratories in Berlin, Germany, by a representative of the United States Treasury Department, that department has refused a license for the importation and sale of their products in interstate traffic.

Correspondence

Tuberculosis is Infectious!

To the Editor:—I desire publicly to correct a serious misrepresentation of my views on infection in tuberculosis that has recently been given wide circulation by a Christian Science journal.

By a *partial* quotation of some conclusions that had summed up the gist of a lecture delivered in Baltimore last May, the above-mentioned article places me in the position of declaring tuberculosis *not* infectious! Nowhere in my conclusions is such a statement made. On the contrary, it was distinctly stated that "childhood is the time of infection" as contrasted with the higher resistance of adults, whose danger of infection was explained as very slight in comparison. It hardly seems necessary to deny such palpable abuse of the truth in this, the twentieth century.

Were it not for the wide-spread use of this article (which was based on an editorial in The Journal of January 3 in which you kindly and fairly commented on the lecture) as a protest against hospital care of the tuberculous, I would bear the unpleasant notoriety in silence.

Not only is tuberculosis infectious, but I firmly believe that the isolation and humane care of the advanced tuberculous patients in hospitals, sanatoriums or homes is the most important and only sure way of preventing infection.

Edward R. Baldwin, M.D., Saranac Lake, N. Y.

Stethophone, Not Stethoscope

To the Editor:—Nonchalantly to say that one is wrong is one thing, but to be correct in saying so is fortunately another.

In The Journal, Dec. 20, 1913, p. 2260, I offered the word "stethophone" as being a better word than "stethoscope." I gave my reasons for the preference and I thought that I had perused my dictionaries sufficiently to be correct in the matter; but in The Journal, Jan. 3, 1914, p. 57, Dr. A. Rose took exceptions to the word, saying that my dictionary was wrong. He also criticized my use of such hybrid terms as "auriscope" and "dictaphone." As to this, I should like to say that I used these terms to make my point clear: that instruments by the use of which we hear should end in the suffix "phone," while instruments by the use of which we see should end in the suffix "scope." It is not my purpose, however, to correct all the wrongs in the medical dictionary. Like Maeterlinck's unborn child, I should find myself with a big job on hand.

It is only too true that our onomatology has not as yet been sufficiently refined.

As to the propriety of the word "stethophone," the following letter is self-explanatory. I have referred it to the Nelsons, who speak authoritatively on such matters.

LETTER FROM NELSON & SONS

Dear Sir:—In reply to your inquiry as to the words "stethoscope" and "stethophone," we think that your criticism is exceedingly good, and that "stethophone," by both analogy and consistency, is by far the better word to denote the instrument used for auscultation.

The following definitions are given in the Century Dictionary:

Stethoscope [Greek, *στῆθος*, the breast, + *σκοπεῖν*, view]. An instrument used in auscultation to convey the sounds from the chest or other part of the patient to the ear of the observer.

Stethoscope (verb). To examine by means of a stethoscope. *Lancet*, 1890, ii, 1267.—Century Dictionary, 1913 edition.

Stethendoscope [Greek, *στῆθος*, the breast, + *ἔνδον* within, + *σκοπεῖν*, view]. A modified form of fluoroscope employed in examination of the chest by means of x-rays.—Supplement to Century Dictionary.

The last-named word, of recent origin, indicating as it does an instrument strictly for ocular use, seems appropriately formed, and in striking contrast to the word "stethoscope."

Under the Greek verb *σκοπέω* we find the following definitions in Liddell and Scott's Greek-English Lexicon: (1) *to look at* or *after* a thing; *to behold, contemplate; look out, watch;* (2) metaph. *to look to, consider, examine, to look to one's* own affairs; (3) *to look out for;* (4) *to inquire, learn;* also, certain forms carry the idea of *deliberate consideration, universal contemplation.*

The primary meaning of the word, however, is evidently that of inspection, view or examination by means of the *eyes*, no suggestion of sound entering into any of its forms. For instance, there are the words *σκοπή*, *σκοπιά*, a *lookout-place*, a *watch-tower*, a *mountain-peak; σκοπός, one that watches*, a *lookout-man*, a *watcher, watchman*, "stationed in some high place (*σκοπιά*) to overlook a country," etc., all denoting the use of the faculty of vision. Hence, we would say that, although, as you say, general usage has permitted the employment of the word "stethoscope" for the instrument used in auscultation, the strictly correct name of such an instrument would be the "stethophone."

In the Standard Dictionary (edition of 1913) is found the word "stethophonometer," thus defined: "a stethoscope with an adjustable slit for measuring the intensity of sounds heard on auscultation." Why "stetho*scope*" and "stetho*phonometer*"? Would it not be more consistent and more euphonious to use a *stethophone* in connection with a *stethophonometer?*

Thomas Nelson & Sons, New York.

So far as I am concerned, this is a closed matter. Stethophone is the proper name for the instrument. Those of smug conventionality may use the time-honored term if they wish.

Joseph H. Barach, M.D., Pittsburgh, Pa.

Blood Transfusion in 1492

To the Editor:—Though a Pepys enthusiast, in my perusal of the "Diary" I had not seen the account of the transfusion of blood cited by Dr. Campbell (The Journal, Jan. 10, 1914, p. 147).

The transfusion of blood, not only experimentally from animal to animal but also therapeutically from man to man, had been attempted long before 1666.

In those books which I have immediately available, to Jean Baptiste Denys of Montpellier, physician to Louis XIV, is usually attributed the honor of having performed the first transfusion of blood in man. He injected, in June, 1667, the blood of a calf or lamb into the veins of a young man dying from repeated venesection. The patient survived and apparently recovered his health. Violent controversies arose regarding the operation, and it was decreed that "for the future no transfusion should be made on the human body but by the approbation of the physicians of *the Parisian Faculty.*"

This official disapprobation and the heavy mortality incident to the practice led to its discontinuance.

One hundred and seventy-five years earlier, in April, 1492, the first transfusion of which we have accurate record occurred in an attempt to prolong the life of Pope Innocent VIII.

The following quotation from Villari's "Life of Savonarola" is self-explanatory:

"The vital powers of Innocent VIII rapidly gave way; he had for some time fallen into a kind of somnolency, which was sometimes so profound that the whole court believed him to be dead. All means to awaken the exhausted vitality had been resorted to in vain, when a Jew doctor proposed to do so by the transfusion, by a new instrument, of the blood of a young person—an experiment which had hitherto only been made on animals.

"Accordingly the blood of the decrepit old pontiff was passed into the veins of a youth, whose blood was transferred into those of the old man. The experiment was tried three times, and at the cost of the lives of three boys, probably from air getting into their veins, but without any effect to save that of the pope."

Previous to this, vague references to such an operation had been made from time to time at least as far back as the Augustan era, both in medical and in lay literature, but I can find no record of any earlier account which approximates the preceding in clarity.

Perhaps some other readers of THE JOURNAL may enlighten me. J. L. JOUGHIN, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

"THE ANATOMIST" OF REMBRANDT

To the Editor:—In my latest copy of THE JOUNAL, I observe under Queries and Minor Notes—to me an always interesting department—an article on Rembrandt's "Lesson in Anatomy." I am one of the many hundreds or thousands of medical men whose sanctum is adorned with a copy of this famous picture, and consequently your account of the origin and vicissitudes of the original is very interesting. There are two circumstances connected with this picture, neither of them historical, to which I should like to refer.

The first is the fact that although the "Lesson in Anatomy" is one of the famous pictures of the world and a favorite with doctors, I have never heard any patient admire it. On the contrary, the only expression of opinion I have heard from the self-appointed connoisseurs who have criticized my copy has been based on abhorrence and disgust of the subject, together with wonder and surprise at my keeping a picture of a horrible "surgical operation" in my office.

The other fact is this: Is not the right arm of the cadaver in the picture, greatly, and in view of the reputation of the artist, egregiously foreshortened? Would a schoolboy drawing a picture of a man with his arm *close to his side make the tips of the fingers* stop above the hip-joint, unless he intended to represent a deformed upper extremity?

In Rembrandt's picture it will be noticed that the tips of the fingers of the right hand reach only to the hip-joint instead of to the middle of the thigh as they should, while on the left side, the arm of which is being dissected by Dr. Tulp for the edification of his Dutch colleagues, the extremity is represented as of normal length. W. M. BARTON, M.D., Washington, D. C.

ACTION OF PIGMENT IN INDELIBLE PENCILS

To the Editor:—In connection with this subject, which was referred to in THE JOURNAL, Jan. 24, 1914, p. 315, I wish to call attention to some work done in Basel, under Carl Mellinger by Dr. Alfred Vogt, in continuation of work done two years previously by Dr. A. Gräflin.

Vogt comes to the following conclusions:

1. The artificial anilin dyes act according to their chemical composition differently on the ocular conjunctiva. From 5 to 10 mg. of the acid, neutral, or "Beizen" colors, as well as those insoluble in water, produce no irritation, or hardly any, on the conjunctival sac of the rabbit. All basic dyes in the same quantity produce serious inflammations, which may progress to panophthalmitis. [Methyl violet, the substance commonly used in indelible pencils, belongs to the basic dyes.—ED.]

2. The toxicity of the basic colors varies in degree. It increases with the basicity, and depends also on other chemical properties, but seems to be independent of the mineral acid of the color-base. The danger increases also with the solubility in the ocular fluid.

3. Experiments on rabbits demonstrate that washing out of the conjunctival sac with a tannin solution of from 5 to 10 per cent. prevents the dangerous effects occurring, while those cases in which the conjunctival sac has been irrigated with water, solutions of sodium chlorid, boric acid, sublimate, and sodium bicarbonate under the same conditions, progress rather more seriously than when left alone.

The articles mention also the literature.

EDMOND E. BLAAUW, M.D., Buffalo, N. Y.

ACIDOSIS—ACID INTOXICATION—CYCLIC VOMITING

To the Editor:—Have epidemics of acid intoxication of children (cyclic vomiting) been reported recently at Concord, N. H., and Birmingham, Ala.? If so, in what publications can I find records of the same? E. F. C., Pennsylvania.

ANSWER.—The newspapers have referred to an "epidemic" of "acidosis" at Concord during December and January with 100 cases and 11 deaths. The secretary of the State Board of Health informs us that there has been an unusual amount of sickness among young children in Concord during the winter, but only a small part of it could be classed under the head of acidosis. In a large number of cases, however, acetone was found in the urine, and they should be classed rather as acetonuria. There have been seven deaths in Concord from acidosis. No unusual number of cases of this affection have been reported from Birmingham, Ala. At this season of the year, when influenza and catarrhal conditions of the nasopharynx are prevalent, acid intoxications are frequently observed in children, and such conditions have been the most frequent exciting cause or most frequent accompaniment of the cases of acid intoxication in both Concord and Birmingham. The affection is a disturbance of metabolism and therefore could not be spoken of correctly as epidemic. Articles on acidosis, acid intoxication and cyclic vomiting have been published as follows:

Parke, Thomas D.: Symptom-Complex of a Series of Intestinal Cases with Pathologic Findings, THE JOURNAL A. M. A., Nov. 30, 1907, p. 827; Further Report on Ileocolitis Complicated by Acidosis, THE JOURNAL A. M. A., Sept. 17, 1910, p. 991.

Sedgwick, J. P.: Studies of Recurrent or Periodic Vomiting, *Am. Jour. Dis. Child.*, April, 1912, p. 209.

Abt, I. A.: Acid Intoxication, *Am. Jour. Med. Sc.*, January, 1914.

Jenkins, T. W.: Acidosis, *Albany Med. Ann.*, December, 1913.

A CLEAN SURGICAL JOURNAL

To the Editor:—In addition to THE JOURNAL, I wish to have the best surgical journal I can get. I like the *Annals of Surgery*, and have but one objection to it: I do not care to help advertise the peculiar class of drugs and appliances to which the publishers of the *Annals* give space. Otherwise it seems to be a most excellent periodical. Please inform me if there is a better that has not this objectionable feature. I am getting the *Southern Medical Journal*. It is the cleanest medical publication I have ever seen, aside from our Association journal. What I want in addition to what I now have is the best surgical journal published, suited to the practitioner in the small town, who does such surgery as comes to him, turning nothing away that he can do.

S. H. LANDRUM, M.D., Altus, Okla.

ANSWER.—The only surgical journal that follows the Council on Pharmacy and Chemistry in censoring its advertisements of proprietary remedies is *Surgery, Gynecology and Obstetrics*. This is published at 31 North State Street, Chicago; the annual subscription price is $10—and it is worth it.

CLEANING SLIDES AND COVERS

To the Editor:—Please give the best method for cleaning old microscope slides and cover-glasses, to remove oil, balsam, old blood-smears, etc. QUIEN.

ANSWER.—Following is the method given by Lee in "The Microtomist's Vade-Mecum":

"Cleaning Slides and Covers: New ones should first be soaked in one of the following liquids: strong sulphuric, hydrochloric or nitric acid, or aqua regia, or a mixture of an ounce each of sulphuric acid and bichromate of potash with from 8 to 12 ounces of water, then washed first with water and lastly with alcohol, and dried with a clean cloth.

"For used ones, if a balsam mount, warm, push the cover into a vessel with xylol or other solvent of the mount, and put the slide into another vessel with the same, leave for a few days, and then put into strong alcohol. If this is not sufficient, treat as for new ones. Some persons boil in compound solution of cresol, which I do not find efficacious."

ARTICLES ON DISEASES OF THE JAW

To the Editor:—Please refer me to the most recent literature on diseases and injuries of the jaws

M D, Nashville, Tenn

NAPOLEON'S SURGEON GENERAL

To the Editor:—In THE JOURNAL, Jan 10, 1914, p 149, under Queries and Minor Notes, there is a reference to the "Works of Napoleon's Surgeon General" I have always been under the impression that my great grandfather, Auguste Baudry, was chief surgeon on Napoleon's staff Have you ever heard of such a person or can you put me in touch with the proper persons to secure such information? We have three medals from Napoleon, two of the crosses of the Legion of Honor, one won during the plague in Egypt

MARY M MOORE, Baltimore, Md

ANSWER—We have made a careful search for Auguste Baudry and have not been able to find any reference to him anywhere, even in the British Museum Catalogue or in Larrey's memoirs of the Egyptian campaign. Larrey became surgeon-in chief of the Consular Guard and its hospital in 1804, and in 1805 Napoleon nominated him *inspecteur du service de santé des armées*. which is the present equivalent of the surgeon general in the French army Baudry may very likely have been a chief surgeon on the staff, which may have been some merely official position, like that of any medical officer designated to serve on the general staff of our army in time of war for special reasons The best way in which this information could be obtained would be to write directly to the Département de la guerre. Paris. France, stating the facts, and the department would undoubtedly comply with the request for information.

REFERENCES TO DISEASES OF THE CAT

To the Editor:—I am anxious to obtain all possible information bearing on the transmission of contagious and infectious diseases by the domestic cat, and also the diseases to which it is commonly susceptible and their possible relation to man

WARREN L. DUFFIELD, M D, Brooklyn, N Y.

ANSWER—Following is a list of references to literature on this subject:

Hill, J. W.: Diseases of the Cat, New York, William R Jenkins Company, 1901. $1 25

PROFESSIONAL SERVICES OF PHYSICIANS TO ONE ANOTHER

To the Editor—Please answer these questions:

1 Dr A treats the child of Dr B, and sends B a bill for services rendered B is uncertain whether or not A knows that B is a doctor of medicine. Shall B pay the bill without comment, or shall B tell A that he (B) is a physician?

2. Under the same conditions except that B undoubtedly knows A has knowledge that B is a doctor of medicine, shall B pay without comment, or accompany the payment with a sharp criticism, or simply disregard the statement?

This situation under the conditions stated, and various other combinations of these conditions, frequently presents itself.

P M D

ANSWER.—1. B should pay the bill without comment.

2. Notwithstanding the added condition, B should pay without comment.

Article II, Chapter II of the "Principles of Medical Ethics" reads:

> SECTION 1—Experience teaches that it is unwise for a physician to treat members of his own family or himself. Consequently, a physician should always cheerfully and gratuitously respond with his professional services to the call of any physician practicing in his vicinity, or of the immediate family dependents of physicians
>
> SEC 2—When a physician from a distance is called on to advise another physician or one of his own family dependents, and the physician to whom the service is rendered is in easy financial circumstances, a compensation that will at least meet the traveling expenses of the visiting physician should be proffered When such a service requires an absence from the accustomed field of professional work of the visitor that might reasonably be expected to entail a pecuniary loss, such loss should, in part at least, be provided for in the compensation offered

An adaptation of these two sections answers the question our correspondent propounds: Dr A renders professional services to one of Dr. B's family dependents; define A's and B's conduct with regard to A's service and B's acceptance of it

First. B has no "right" to A's professional services unless B is engaged in the practice of medicine in A's vicinity. If B gains his livelihood from a source other than the practice of medicine, he should not expect A's gratuitous professional services.

Second. If A fails to respond with "gratuitous" service to a dependent member of B's family, A sins against the ideals of the profession rather than against B, the individual physician practicing in A's vicinity. It is the profession at large, rather than B, who should call A to account for his neglect of the opportunity presented by B's necessity.

TREATMENT OF HYDROFLUORIC ACID BURNS

To the Editor:—What is the best treatment of burns made by hydrofluoric acid?

C C DUBOIS, M D, Warsaw, Ind

ANSWER—The burns should be washed with diluted milk of magnesia Ammonia is too caustic. Reference may be made to the following:

Desoignes *Am Jour Pharm*, October, 1890, p 494, from *Répert de pharm*, Sept 10, 1890; abstr, *Proc. Am. Pharm Assn*, 1891, xxxix, 494
Branson, Laura H Physical Injuries as Results of Hydrofluoric Acid THE JOURNAL, Aug 10, 1912, p 436

HEX-A-LITH

To the Editor:—The Smith-Dorsey Company, of Lincoln, Neb, puts out a preparation under the title of Hex a lith which is a combination of hexamethylenamin with lithium citrate What is the physiologic effect of such a combination? [illegible] the lithium citrate should have the tendenc [illegible] alkaline, and we have been taught that [illegible] act only in an acid medium

FRED W. PHIFER, M D, Wheatland, Wyo

ANSWER—The lithium citrate would render the urine alkaline and defeat the object of administering hexamethylenamin.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

WISCONSIN'S EXPERIMENT IN MARRIAGE REGULATION

Probably no law of recent enactment has caused the amount of general discussion in the press that has been aroused by the law adopted at the last session of the Wisconsin legislature, requiring a physician's certificate of immunity from venereal disease on the part of the groom as a preliminary to the issuing of a marriage license. Although the law was enacted early in the year, but little attention was apparently paid to it until the time of its enforcement was near at hand. It went into effect Jan. 1, 1914. Apparently neither the medical profession nor the public realized its significance until the form of the medical certificate was brought to the attention of physicians. Then it at once became evident that the law, like so much of our legislation, had been hurriedly drafted and was loose in construction, vague in meaning and capable of various interpretations. It provided that each male applicant for a marriage license should present a certificate in the form of an affidavit from a reputable physician, stating that the latter had subjected the applicant to "all of the known and recognized tests known to medical science," and had found him free from venereal infection. For making these examinations and executing the certificate the physician was allowed a maximum compensation of $3.

The united protest which arose from Wisconsin physicians was, in reality, a protest against a law which physicians knew to be practically impossible. Unfortunately, these objections were at first placed before the public in such a way as to carry the impression that the opposition of physicians was entirely due to the amount of the fee. The first editorial comments which appeared in the newspapers, both in Wisconsin and throughout the country, were evidently hastily written, without a knowledge of the facts, and were largely criticisms of the attitude taken by physicians. It is only fair to say that practically all of the newspapers, after the real facts became known, withdrew their criticisms and adopted the same position as that taken by the medical profession.

While in some cases individual physicians or medical organizations acted hastily or spoke unwisely or intemperately, the bulk of the Wisconsin profession acted admirably, simply reiterating at every opportunity that the law required physicians to swear to a statement of facts, the acquisition of which would require repeated examinations, for weeks, if not months, the possession of an elaborate and expensive equipment and a technical training possessed only by a few. From a scientific point of view, under present conditions the enforcement of such a law is impossible, regardless of the amount of the fee. The average physician cannot make a Wassermann test, even if he were provided with the necessary equipment.

As announced in our editorial columns,[1] the law was declared unconstitutional by the first judge before whom a case involving it was taken. While this decision of the lower court is subject to the review of the appellate and supreme courts, the inequity of the law is such as to make it practically certain that it will be held void by the court of last resort.

This, in brief, is the history of one of the most instructive experiments in advanced legislation that the country has seen for some time. The good effect of Wisconsin's experience is manifest in other states. It is safe to say that neither this winter nor next will see the flood of absurd and impracticable bills on all public health topics with which our legislatures were deluged last winter. The general public, the law-making bodies, the sociologists and the medical profession must all learn that while there is a legitimate field for constructive public health legislation, there are also definite limits for such efforts and that there are many subjects which cannot be regulated by law, however desirable such regulation may appear. It is highly desirable that future wives and mothers should be protected against marriage with diseased men. When we have reached a point in public enlightenment at which public sentiment demands such protection, it will then be necessary to devise some way in which the state can secure such information through properly conducted official channels. To attempt to establish, by law, a standard which is scientifically impossible on a basis of compensation which is economically ridiculous can only bring such efforts into disrepute and result in failure.

Following the enactment of the law, criticisms of physicians in the newspapers varied all the way from the comment of the Racine (Wis.) *Times*, which under the title "Greed and Doctors" made the startling statement that any doctor in the state could afford "to spare the few minutes required to make the cursory examination without any fee at all, and that the $3 is fair pay, everything considered," to the Los Angeles *Times*, which said: "The average doctor is a busy man. . . . To satisfy the needs of the eugenic examination it would be necessary to make in each case an examination of all the organs and to do it well; otherwise the aim of the eugenists would be defeated and the whole thing would be a farce. It is preposterous to expect reputable physicians to make such a series of tests for $3. Besides, they have really sick people to look after."

It soon became evident to every one interested that the difficulty was not alone in the size of the fee, but that other serious objections must be considered. After enumerating the necessary steps of an examination which would enable a physician to make affidavit to the condition of the applicant, the New York *Tribune* expresses the fear "that the work will fall into the hands of unscrupulous practitioners, whose examinations will not comply with the legal requirements and that thus the system will become delusive." After reviewing the discussion before the Milwaukee County Medical Society, the Milwaukee *Evening Post* points out what the literal enforcement of the law would mean to physicians as far as work and responsibility are concerned, and says: "Holding these views, is it wonderful that they [Milwaukee physicians] proclaim the enactment ill advised? . . . The protection of the innocent, the safeguarding of health of those yet unborn. these are objects worthy of the utmost vigilance on the part of members of the medical profession, and of all good men and women as well. . . . That the legislature attempted to place on the statute books a chapter intended to effect this object is creditable to all concerned. Since the enactment is impracticable, it behooves the collective wisdom of the community to devise practical precautions to meet the need which this tentative effort of the law-makers was meant to subserve."

Summarizing the practical objections to the law, the Beloit (Wis.) *News* feels that the object aimed at, "to protect innocent women who are now subject to untold suffering because of the diseases of the men they marry," is most commendable, and that a way should be found to make the provisions of the law applicable. The El Paso (Tex.) *Herald*, on the other hand, anticipates that the only good which will result will be the stimulation of public sentiment. It says truly that "in eugenics a little knowledge is a very dangerous thing, but if out of the whirlwind of talk and discussion that has swept through the minds of men lately mothers learn to teach their children a bit more honestly about sex, and parents learn to protect their daughters from men known to be immoral, and if sons are honestly warned against the results of vice, the world will have gained a little." The Wausau (Wis.) *Record*, criticizing the law as a sample of progressive legislation, condemns the entire principle of regulation. which according to the editor, has proved a failure repeatedly in the past. "There is not a commission in Wisconsin whose prototype did not exist two thousand years ago, not a feature of the whole idea but has been worn threadbare as an instrument of tyranny by the nations now in ruin." Greece and

---

[1] The Wisconsin Marriage Law Declared Unconstitutional, editorial, THE JOURNAL A. M. A., Jan. 24, 1914, p. 305.

Rome, medieval Europe and English parliamentary government are all arraigned as witnesses of the folly of regulation. The *Record* concludes that "it is time for the misguided population to wake up and grasp the fact that the whole course of civilization has been away from rather than toward the sort of thing that the oligarchy at Madison is setting up, and to learn that true progress now and always means the liberation of the people from slavish and degrading official supervision."

The Elgin (Ill.) *Courier*, after insisting that the state has no right to fix a definite limit for an indefinite amount of professional services, and that, on the other hand, "the tendency of the times is too much in the direction of rule-making," says that "the state might do far better if it did more for the child that is inevitably going astray and pay less attention to adults who have already blundered." The editor feels, however, that such laws can do no great amount of harm and that their principal function is to "mark the passing of time and, in the meantime, education is being made more accessible, and perhaps it is education and nothing else that can correct the evils which have engaged the attention of the eugenists."

The Louisville (Ky.) *Herald* quotes an eminent Wisconsin lawyer to the effect that the law is an unconstitutional infringement of individual rights, and while declaring its complete sympathy with the objects sought by the more conservative proponents of eugenics, the editor still holds that "the law has limits. Certain social problems must be solved otherwise than by statute. . . . The remedy for the evil . . . seems to lie in education rather than in legislation. Let parents be instructed to guard their sons and daughters against ill-advised marriages. Let the parents, instead of the law, demand certificates of health from prospective wedding principals. Teach the sons and daughters that other requirements in addition to love are essential to happiness in marriage. Without such instruction the most stringent law . . . stands a chance of being a dead letter. With such instruction no law is needed."

The Milwaukee *Sentinel*, after criticizing the law as it passed, undertakes some "constructive suggestions" for the consideration of future legislatures. The *Sentinel* asks, "if we are to have a statute for the public regulation of marriages . . . why not provide for its public administration? Medical discussion and ridicule of the statute has brought out the fact that the average private practitioner is totally incompetent, and in point of apparatus utterly unfurnished for the required tests. . . . The private practitioner's difficulty seems to point plainly to the public doctor and public equipment . . . as the proper recourse. If we are to have such a statute at all, it ought to be made effective for its good purposes by proper administrative provisions. That would involve a system of regularly constituted medical examiners and a state equipment for the really requisite tests."

The same sentiment is expressed by a number of other Wisconsin editors who, after considerable discussion, have finally taken the ground that if the public good required it and the state had the authority to restrict marriage to those who were able to comply with certain physical standards, then the question of determining who are fit for marriage rests on the state and not on the medical profession, and that if the state desired medical services in performing any of its functions, then it should provide those services on a proper basis. Various loopholes and subterfuges for the evasion of the law were pointed out. The attorney-general of the state attempted to put a "reasonable" interpretation on the law by holding that the provision requiring the application of "all known scientific tests" meant only an application of those with which the individual physician happened to be familiar and able to apply. The result of such a ruling would have been that the value of the certificate in each case would have depended entirely on the knowledge and ability of the physician signing it. A Milwaukee attorney tried to solve the puzzle by calling attention to the fact that, under the common law, no marriage ceremony was necessary and that only the filing of a mutual agreement to live together as husband and wife was required to constitute legal marriage in the state. As the legal fee for filing such a document would be only ten cents, this suggestion was hailed as a solution of the problem that was at once practical and economic.

About this time Hon. Bird C. Coler, in an address in Chicago, threw a flood of white light on the situation. Mr. Coler, assuming for the time being the rôle of a prophet, predicted that if children were taught eugenics in the public school the race would die out in one hundred and fifty years. Mr. Coler did not submit the mathematical calculations by which he arrived at this definite conclusion, but advanced, as proof of his assertion, the birth-statistics of the graduates of a woman's college in which sex hygiene had been taught for some time past. Mr. Coler's reasoning seems to have been thus: The graduates of a certain woman's college have given birth to few children. Sex hygiene has been taught in this school for many years, therefore, sex hygiene is responsible for the low birth-rate among the graduates. Mr. Coler's peculiar brand of logic is referred to newspaper paragraphers as an almost unlimited inspiration for mirth. His contribution was quickly taken up and widely commented on, without any great amount of enlightenment resulting.

Another curious development was the objection raised by Milwaukee merchants, who found that in the three weeks of January during which the legal situation was under discussion marriages decreased so much as to injure their business. During the first two weeks of January only five marriage licenses were issued in Milwaukee, as compared with 250 in the same period last year. The Chicago *Post* states that it is estimated that every married couple spends an average of $300 on house furnishings, clothing and other necessities during the first two weeks of married life, and that this amounts to a loss to Milwaukee merchants of about $75,000 in that time. This estimate maintained through the year would amount to over $4,000,000. The *Post* observes that "the fact that probably much of this money is being spent on cigars, drinks, candy and theater-tickets will not comfort the dealers in household furnishings." Fortunately, the decision of the court has probably, by this time, rescued Milwaukee merchants from the danger of bankruptcy.

These editorial opinions and comments might be multiplied almost without limit. After careful and critical perusal of views from all parts of the country, one is inclined to regard the opinion of the Columbus (Ohio) *Dispatch* as the conclusion of the whole matter. "The Wisconsin law is a model all right, although not of what was intended. It is, instead, a model of legislative ignorance and haste."

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Connecticut: New Haven, March 10. Sec., Dr. Charles A. Tuttle, New Haven. Homeopathic: New Haven, March 10. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Eclectic: New Haven, March 10. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Maine: Portland, March 10-11. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Massachusetts: Boston, March 10-12. Sec., Dr. Walter P. Bowers, Room 159, State House, Boston.

Wyoming: Laramie, March 10-12. Sec., Dr. H. E. McCollum, Laramie.

Tennessee May Report

Dr. A. B. DeLoach, secretary of the Tennessee State Board of Medical Examiners, reports the written examination held at Memphis, Nashville and Knoxville, May 1-2, 1913. The number of subjects examined in was 8, total number of questions asked, 64; percentage required to pass, 75. The total number of candidates examined was 400, including 173 non-graduates, of whom 306 passed, including 122 non-graduates and 94 failed, including 51 non-graduates. The following colleges were represented:

SURGERY

1. How would you treat acute traumatic synovitis of the knee-joint? 2. Should splints be applied in flexed or straight position in a fracture of the olecranon process? Why? 3. Describe a typical case of acute prostatitis. What treatment should be employed? 4. What is meant by McBurney's incision for appendicitis, and why made? 5. What treatment should be employed in a compound fracture of the astragalus? What is the usual result of such an injury? 6. Define shock and give treatment. 7. Define ulcer, abscess and fistula. Give *treatment of each.* 8. What is meant by Pott's fracture? Give treatment. 9. Differentiate benign and malignant tumors. Name two of each. 10. Describe briefly the preparation of patient for laparotomy.

ANATOMY AND EMBRYOLOGY

1. Describe the clavicle. 2. Describe the lateral ventricles of the brain. 3. Describe the axilla. 4. Name the extensors of the fingers and give their nerve supply. 5. Describe the blood-vessels of the walls of the heart. 6. Describe the mesentery and name the viscera supplied with this structure. 7. Name the bones and ligaments entering into the formation of the knee-joint. 8. Name the ductless glands. 9. Define zona pellucida, centrosome, mesoderm, urachus, ductus arteriosus. 10. Describe the blood-vessels of the placenta.

BACTERIOLOGY AND HYGIENE

1. What are bacteria? What general purpose do they serve in the economy of nature? 2. What is a virus? How attenuated? 3. Give two methods of producing artificial immunity against infectious diseases. 4. Of what value is bacteriology in the diagnosis of syphilis? 5. What proof is necessary to demonstrate a causal relation between a given bacterial species and a disease. 6. What are occupational diseases? Give three examples. 7. Name five diseases of which impure milk is a carrier. 8. How would you disinfect a room in which a patient suffering from a contagious disease had died? 9. What is a disinfectant? Name three effective for general purposes. 10. Discuss mode of dissemination of typhoid fever.

OBSTETRICS AND GYNECOLOGY

1. Describe a normal labor, its stages and its management. 2. Give the diameter and boundaries of the inlet to the true pelvis. 3. Give the symptoms and treatment of puerperal septicemia. 4. What do you regard as the best method of delivery in an occipitoposterior position when the head fails to engage? 5. What movements, when complete, constitute the mechanism of labor? 6. Give your technic in the examination of a gynecological case in your office. 7. Treatment of gonorrhea in the female; name its complications and their treatment. 8. Differentiate uterine fibroid tumor, pregnancy and tumors of ovary. 9. Diagnosis, prognosis and treatment of carcinoma of uterus. 10. Name the most common displacements of the uterus.

SPECIAL MEDICINE

1.Give the principal points required in taking the history of a case. 2. Give points on the chest at which the four principal heart murmurs are heard. 3. What is meant by myopia, hypermetropia, and how is each corrected? 4. Describe a case of ophthalmia neonatorum; give cause and prevention. 5. Hay fever; give cause, symptoms and treatment. 6. Epistaxis; give cause and treatment. 7. Laryngoscope; describe method of use. 8. Follicular pharyngitis; describe symptoms and treatment. 9. Hardened ear wax; give symptoms and treatment. 10. Abscess of middle ear; how diagnose and treat.

CHEMISTRY AND MEDICAL JURISPRUDENCE

1. Name three inorganic acids and give their elementary composition. 2. Define atom and molecule. 3. What is the source of glycerine? What four simple elements are always found in proteids? 5. Give test for blood in urine. 6. Give test for bile in urine. 7. Give chemical formulas for: nitric acid; sulphuric acid; hydrochloric acid. 8. Give the chemical name and formula for Epsom salts. 9. What is an antidote for phenol when a poisonous quantity has been taken? 10. What would be the proper thing to do should you find a person apparently dead on the public road?

PHYSIOLOGY AND HISTOLOGY

1. What is the source of animal heat, and how is the temperature of the body maintained? 2. What is the composition and action of the bile? 3. Describe the course and changes nitrogenous foods undergo in the body. 4. Give the physiological action of the pneumogastric nerve 5. Red corpuscles: Describe them, where formed and destroyed. Give function. 6. What is the effect of the use of alcohol long continued, on the human body? 7. Define secretion, excretion and assimilation. 8. What changes are produced in the air and in the blood by respiration? 9. Give the histological structure of the kidneys. 10. Give histology of the skin.

MATERIA MEDICA AND THERAPEUTICS

1. Strychnin: From what derived, dose, effect on heart and respiration? 2. Codein: From what derived, dose, what effect upon

respiration. Give therapy. 3. Digitalis: Dose of tincture, effect on heart and pulse, therapeutic uses, when contra-indicated. 4. Give dose of (1) atropin sulphus, (2) hyoscin, (3) cocain, (4) apomorphin, (5) hydrargyri chloridum corrosivum. (6) hydrargyri chloridum mite, (7) potassii et sodii tartras, (8) liquor potassii arsenitis, (9) oleum ricini, (10) oleum morrhuae. 5. Antidote for (1) oxalic acid, (2) opium, (3) nitric acid, (4) iodin, (5) arsenic, (6 corrosive sublimate, (7) lye, (8) phosphorus, (9) silver nitrate, (10) antimonii et potassii tartras. 6. Name three cardiac stimulants, give adult dose, and dose for child two years old. 7. Write a prescription containing not less than three drugs for an adult suffering with dysentery. 8. Adult with history of having taken some drug, rapid breathing and pulse, red efflorescence of skin, active talkative delirium, dry throat, a few convulsions, dilated pupils, diagnosis and treatment. 9. Fluid extract of ergot: Therapeutic use and contra-indications. 10. Acetanilid: Therapeutic use, dose and symptoms of poisoning.

PRACTICE AND PEDIATRICS

1. Define, diagnose and treat acute articular rheumatism. 2. Give the etiology, symptoms and treatment of pernicious anemia. 3. Give the etiology, diagnose and treat typhoid fever. 4. Give the etiology, diagnosis and treatment of diabetes mellitus. 5. Define, diagnose and treat tetanus. 6. Give symptoms and treatment of erysipelas. 7. Describe the physical signs and symptoms of lobar pneumonia. Give treatment. 8. Discuss the etiology and treatment of exophthalmic goiter. 9. Define, diagnose and treat acute poliomyelitis. 10. Discuss the etiology, give symptoms and treatment of chorea.

Iowa January Reciprocity Report

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the number of candidates licensed through reciprocity, Jan. 14, 1914. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

Indiana Medical College	(1906)	Indiana
John A. Creighton Medical College	(1911)	Nebraska
Lincoln Medical College	(1908)	Nebraska

Book Notices

Manual of Obstetrics. By John Osborn Polak, M.Sc., M.D., Professor of Obstetrics and Gynecology in the Long Island College Hospital. Leather. Price, $3 net. Pp. 468, with 122 illustrations. New York: D. Appleton & Co., 1913.

The object of this volume, as frankly set forth, is to place the essential facts and principles of obstetrics within the easy grasp of the student. It is intended as a systematic introduction to the more elaborate treatises, and as a guide in following didactic and practical teaching of the college courses. In preparing a volume of such a nature, brevity is the desideratum. Hence most attention has been given to practical topics, theoretical discussions and elaboration of detail being excluded. The chapters are long but carefully subdivided, such divisions being indicated by bold-faced type. Subheadings are also prominent, and the arrangement of subject-matter and text is such that the student will be able readily to get the important points. The essentials are well formulated and compactly set forth in convenient grouping or in tables. Thus the embryology of the genitalia, the development of the ovum, the signs of pregnancy, preparation for labor and many such topics are fully presented, yet made to occupy a minimum of space. For so compact a presentation the illustrations are abundant and, for the most part, good. Space is given to artificial feeding and to disorders of the new-born infant. No dispute can be entered into with the author as to his position in debatable points, since he has omitted all argument.

Syphilis and the Nervous System, for Practitioners, Neurologists and Syphilologists. By Dr. Max Nonne, Chief of the Nervous Department in the General Hospital, Hamburg. Authorized Translation from the Second German Edition, by Charles R. Ball, B.A., M.D., Chief of the Nervous and Mental Department, St. Paul Free Dispensary. Cloth. Price, $4. Pp. 406, with 98 illustrations. Philadelphia J. B. Lippincott Company, 1913.

Nonne's book on nervous syphilis, of which this is a translation, has already become a classic. Though the first edition appeared only six years ago, citations from it appear everywhere. Not only does the author expound the so-called "four reactions" for nervous syphilis, on which he has expended much labor, but he also tells the story of syphilis of the nervous system in a manner not heretofore attempted by anyone. The book is written in an easy conversational style, divided into nineteen lectures. Much to the regret of English readers, until this translation appeared, no one seemed sufficiently enthusiastic and industrious to begin work on an English translation. It was left for Dr. Ball, an ardent admirer and former student of Dr. Nonne, to accomplish the task of translating his master's book. In common with many other translations from the German, it shares the fault of being too literal. It may appear trite for us to be obliged to reiterate that enthusiasm and industry are not the only requisites for furnishing a good translation of a foreign book. In our opinion, a translator must be master of at least two languages, the one from which he translates and the other into which he translates. In the majority of instances, the mastery embraces one language and a dictionary. In spite of its shortcomings, and there are many, this translation is better than none at all. Because of the well-deserved reputation of its author, the book should find a large reading public.

In Memory of Dr. James Livingstone Thompson, 1832-1913, and His Son, Dr Daniel A. Thompson, 1862-1904. By the Indianapolis Literary Club, the Indianapolis Medical Society, the Loyal Legion of Indiana and Others. Paper. Pp. 98. Indianapolis, 1913.

The extent and the manner in which character and individuality impress themselves on a community, a state or a nation are always interesting, though perhaps impossible of exact measurement and description. It is usually only after men possessing these qualities have passed away that an approximate estimate of their influence in a variety of relations can be made. The profession should be proud of medical men of this type. Such a man was Dr. James L. Thompson of Indiana, a pioneer in ophthalmology who, with his teacher, Dr. Elkanah Williams of Cincinnati, was one of the first men in this country to devote his attention exclusively to this branch. As citizen, physician, soldier and author, a man of great force of character, Dr. Thompson touched the life of his community and the affairs of his profession at many points, and everywhere, as was said of him, "his supremacy was acknowledged by all." His high qualities have stirred his friends to prepare this little memorial, contributed to by a poet, a lay and a medical editor, an author and a number of his brother physicians and others, who have here attempted to express their appreciation of the man.

Industrial Poisoning from Fumes, Gases and Poisons of Manufacturing Processes. By Dr. J. Rambousek, Professor of Factory Hygiene, Prague. Translated and Edited by Thomas M. Legge, M.D., D.P.H., H.M., Inspector of Factories. Cloth. Price, $3.50 net. Pp. 360, with illustrations. New York: Longmans, Green & Co., 1913.

"The book is intended," the author says, "for all who are, or are obliged to be, or ought to be, interested in industrial poisoning." Occupational diseases have been much studied recently. This work was selected by the translator and editor because it seemed to treat the subject in comprehensive and systematic manner within the compass of a small volume. Numerous references to the subject are included in a special appendix. The book is well illustrated with diagrams of apparatus employed for various industries and numerous instances of actual cases of poisoning are quoted. It is interesting and worth while.

Diseases and Injuries of the Eye. A Text-Book for Students and Practitioners. By William George Sym, M.D., F.R.C.S.E. Ophthalmic Surgeon, Edinburgh Royal Infirmary. Cloth. Price, $2.50 net. Pp. 493, with 114 illustrations. New York: The Macmillan Company, 1913.

This book is one of the Edinburgh Medical Series, general editor, John D. Combie, and was probably written at the behest of the editor or publisher for the purpose of filling a place in a series. There does not appear to be any other reason for its existence. The book presents its subject as well as do other numerous similar books. The size of the book is a virtue—it at least is not so pretentious as are some of the larger unnecessary books.

Miscellany

The Declining Birth-Rate.—Among the many expressions of opinion which have been made on the advancing reduction of births in Germany, that of the hygienist, von Gruber of Munich, delivered in the German Association for Public Health must be accorded great significance. The number of births in Germany has steadily decreased from 1876, when it amounted to 426 per ten thousand inhabitants, and since the year 1900 there has occurred a constantly more marked reduction. In 1911, the number sunk about 60,000. The excess of births in 1906 was 149 per ten thousand; in 1911 it was only 113. In the kingdom of Saxony, which was formerly extraordinarily fruitful in children, the reduction has been most marked. In that kingdom the birth-rate has diminished since 1876 by about 40 per cent. The reduction in the fertility of the country women must be especially emphasized because the country was the one real hope and support. The birth-rate has undergone a more marked reduction in Protestant than in Roman Catholic districts. Moreover, there is a certain relation to the political complexion of the locality, for in general those districts in which the representative is a social democrat show a more marked reduction. In Berlin the birth-rate dropped in the period from 1876 to 1912 from 149 to 73, and the legitimate fertility from 240 to 80, that is, to one-third. The reduction is still more marked in the suburbs. The birth-rate of Berlin is no longer sufficient to maintain the present number of the population by its own increase. The important reduction in the last three years is chiefly to be attributed to the fact that extensive circles of the working population are now beginning to follow the example of the well-to-do. A circular query of the Imperial postal department for the year 1911 showed that of the upper employees nearly 16 per cent. are unmarried and of the under clerks not 4 per cent., and that 20 per cent. of the marriages of the higher officials were childless and of those of the under clerks only 13 per cent., and that the children to a marriage of the higher officials average 1.8 and of the under clerks 2.4.

Von Gruber spoke of the influence of venereal diseases and of alcoholism on the reduction in births, which shows itself naturally chiefly in the large cities. In reduction in births voluntary prevention plays a decisive rôle. The birth-rate of southern Slavic people is high. There is little help to be expected from the free play of the forces involved, or else a change would already have occurred in the condition of France, where the need of the fatherland with reference to the reduction in births is plainly seen and where such ardent patriotism reigns. Instead of this there are many districts in France in which there are more deaths than births. France would already have a negative birth-rate if the lack was not supplied by foreigners, especially the Italians. The changed relations of the family, the greater freedom of women and their increasing participation in industry, together with the fear of loss of health and prosperity with many children, favor the restriction of the birth-rate. The fear as to the health of women is unwarranted since it is shown that up to ten children the health of the mother is not materially affected. Nor is poverty a legitimate excuse since there never was a time when the families of workmen were more prosperous than at the present day. The entire population has been permeated with neomalthusianism and with the desire to live a life with less care, less risk, a more comfortable and refined life. This impression is increased by the doctrine of individualism that every one's highest aim in life should be and must be himself. The author emphasized the economic disadvantages of a *stationary* population. Already in France industry and agriculture are at a standstill.

Reduction in the death-rate, especially in infant mortality, cannot possibly compensate for the fall in the birth-rate. In order to overcome the two-child system, two measures especially are requisite: first, a change in our ideals so that the raising of a numerous and healthy posterity shall be regarded as the highest duty of every man; second, the provision of such economic conditions as are required for the rational bringing up of a sufficient number of children. Large sums must be devoted yearly to this purpose, and so applied not only that there shall be a sufficient number of offspring, but also that their health shall be assured. This aim is not to be secured by means of the so-called emancipation of women, by free love and the education of children by the state. . . . In his conclusion, von Gruber spoke with great decision against the advocates of women's rights. They protest against being merely child-bearing machines, as if that were their only function, as if they had not also the task of bringing up their children. They wish now to become thinking machines. But they should leave that to the men whose entire bringing up equips them better for it, for consistency has never been the heritage of the female sex.

The Deformities of Illustrious Men.—In his presidential address at the twenty-sixth annual meeting of French surgeons held in Paris recently, Dr. Kirmisson mentioned among the illustrious men who have been deformed, Tyrtaeus, the lyric poet, who was lame, and Aesop, the fabulist, whose bust by Thorwaldsen shows the deformity of Pott's disease; Alexander the Great, who had torticollis; Soult, Talleyrand, Walter Scott and Lord Byron. Soult's infirmity was not congenital, but was caused by a wound in war. As for Walter Scott, Kirmisson concludes from the information furnished by Scott's autobiography that the cause of his lameness was infantile paralysis, which produced an equinism. One of his biographers, Robert Chambers, says that he rested his weight on the tips of his toes. At the end of two years he began to walk by the aid of crutches. It is difficult to procure exact information with regard to the deformity of Talleyrand. Kirmisson was able to study a shoe of Talleyrand's recently bequeathed to the Carnavalet Museum in Paris, which indicates that the deformity was an equinovarus of the right foot. In the case of Byron, also, a pair of orthopedic shoes made for him as a child, which are in the possession of Murray, the English publisher, indicates the same deformity as in Talleyrand's case. This agrees with a letter written by his mother when the child was 3 years old, saying: "George's right foot turns in. He walks almost entirely on the side of the foot." It also agrees with the description in the *Lancet* by Sheldrake, who was commissioned to make orthopedic shoes for Byron. If the deformity in question seems not to have troubled Talleyrand greatly, it was a veritable torture for Byron. "When one sees what a source of physical and moral torture a deformity may be," remarked Kirmisson, "one realizes the benefit of orthopedic surgery."

Decompressive Trephining in Cerebral Hemorrhage.—Dr. Pierre Marie, professor of pathologic anatomy at the Académie de médecine, read before the Faculté de medécine de Paris an important paper on this subject. The comparison of clinical facts and anatomopathologic lesions of the brain in cerebral hemorrhage leads to the conclusion that the coma is due much less to the sudden irruption of a considerable mass of blood in the interior of the affected hemisphere than to the compression of the brain caused by the presence of this quantity of blood. The sudden irruption of the blood produces ictus, which is a transitory phenomenon; the compression of the brain produces coma, which is a persistent phenomenon, but a deep and lasting coma is not produced unless the opposite hemisphere is compressed also. Pierre Marie was able in several instances to demonstrate the fact that a focus of cerebral hemorrhage, even when very large, from 5 to 6 cm. in length and from 3 to 4 in breadth, does not produce coma if it does not lead to compression of the opposite hemisphere. Conversation may be carried on with the patient; he retains enough consciousness to answer questions and to make gestures which he is told to make. When the unaffected hemisphere is compressed, however, the coma is profound and absolute. The patient has lost all relations with the exterior world. The importance of the compression of the sound hemisphere in the production of coma is great, for it leads to a very simple and logical therapeutic conclusion, the necessity for decompressive trephining. But what region of the cranium shall be trephined? If the trephining is done on the side of the hemorrhage, the patient is subjected to many dangers. In the first place, there is the great risk of augmenting the hemorrhage. Pierre Marie therefore proposed decompressive trephining on the side of the sound hemisphere. The advantages are evident: (1) the influence of operative traumatism on the focus of the hemorrhage is reduced to the minimum; (2) there is no fear that the hemorrhagic focus will bleed in the meninges, since the bony wall is intact next to it; (3) decompression of the healthy hemisphere is made as quickly as possible. Pierre Marie does not propose to operate in every case of cerebral hemorrhage. Age is a contra-indication, for among the old bronchopulmonary complications make the prognosis dubious. A very pronounced albuminary syndrome is also a contra-indication. It is preferable to operate on patients before their temperature rises, for then secondary infections may play an injurious rôle. When the coma is complete, from the first hours, it is to be feared that on account of the enormous quantity of blood which has escaped or the extent of the focus toward the base of the brain, decompressive operation will be ineffective. All these considerations apply equally to certain forms of massive softening in the sylvian tract, which, by an intense inflammatory edema in the softened hemisphere, produces pronounced compression of the sound hemisphere.

Care of the New-Born.—On the second day, after both mother and infant have had a good rest, let the baby take the breast once or, at most, twice, so that he can get some colostrum, which by this time will be present in larger quantities in the breasts, so as to clean out his bowels of meconium. If he cries much give him water, as much as he wants. On the third day have him nurse three times, four on the fourth day, and from the fifth day on feed him every four hours in daytime, but never at night, thus giving him five feedings daily, usually at 6 and 10 a. m. and at 2, 6, and 10 p. m. If he sleeps, never allow him to be awakened, but you will be surprised to see how soon the little ones get accustomed to this regime and how well they know when it is time for nursing. Try this regime once yourselves; observe the rested condition of the mothers after they have had a full night's rest every night from the time the baby is born; note how they have a plentiful supply of good milk without resorting to any specially disagreeable and nauseating diet consisting of over-large amounts of liquids which are supposed to produce milk, while as a matter of fact, they do not, but rather prevent it (and let me here add that I allow my puerperae to eat anything they want after they have had their first refreshing sleep, and that I do no longer place any restrictions on their diet, as long as they are getting sufficient nourishment and keep in good health); observe also the good condition of the babies, how quietly they sleep and the look of contentment on their faces; try it only once and I am sure you will become as enthusiastic adherents of this method as I am myself.—Carl G. Leo-Wolf, M.D., in *New York State Jour. Med.*

Journalistic Suggestions for Medical Writers.—Eliot in the *Pennsylvania Medical Journal* discusses this subject from the point of view of the editor. He says that it is an unfortunate trait of the average man to desire to see his name in print, but it is hard to convince some writers that their productions are excellent from a literary point of view but useless from that of editorial policy. He says that many carefully prepared papers sent to journals on account of their large circulation rather than the adaptability of the paper to the journal are returned as unavailable, to the great disappointment of the author. If he is reasonable, however, he will ask himself whether the paper was such as to hold the attention of the general reader, and will also remember that he is not paying for the printing. Eliot then calls attention to some things which the author of a paper should keep in mind in preparing his manuscript. He should have some system and should divide his subject into headings, placing all the ideas under each heading which properly belong to it. The reader does not care for the author's titles and appointments, but is interested only in what he has to say, and expects him to say it in the fewest possible words. Illustrations, temperature charts, etc., should always be on separate sheets, and illustrations should illustrate and not show instruments, apparatus or forms of disease of common use or of daily observation. The paper should be sent to one journal only. The title should express the subject; the shorter it is, the better. Introductions are seldom of any value except as pieces of vanity on the part of the writer. An apology for a paper is an admission of mediocrity and few will read it. Quotations tend to weaken a paper. A short abstract of the points to which it is desired to make references is better. A long list of references is undesirable. Authors interested in the subject will verify the work from the literature. The names of hospitals, sanatoriums, asylums and homes, or the names of manufacturing houses, should not be given, lest the paper be taken for an advertisement. Long case histories are usually unnecessary; names of consultants, assistants and others are uninteresting. Nobody cares who was present or who assisted, but everybody wants to know the essential points of what was done and how it was done. (It might be added that the disjointed, telegram style of case reports is objectionable.)

The Eyeball-Heart Reflex.—Loeper and Mougeot reported research last year confirming the instructive import of Aschner's reflex, the slowing of the heart-beat when pressure is applied to the eyeballs. In two or three seconds at most, the heart slows up by about 8 beats to the minute, but the former rate returns as soon as the pressure is released. In tabes this reflex seems to be abolished. In some cases the absence of the oculocardiac reflex, as they call it, was the first sign to attract attention to the tabes. The apparently paradoxic tachycardia with abnormally high blood-pressure does not affect this reflex, but this tachycardia warns of impending breakdown of the left heart and calls for digitalis unless it yields to other measures. They explain the mechanism of this tachycardia, saying that the eyeball-heart reflex first threw light on it. They published several communications on the reflex in the *Progrès médical*, 1913, xli, 211, 663 and 675. With a gastric neurosis this reflex is an indication whether the pneumogastric or the vagus is predominantly involved, and this may prove a guide to treatment. In one of the cases reported the patient had an ulcer on the lesser curvature, and the pulse slowed up by 14 beats on pressure of the eyeballs. Three months after resection of the stomach the pressure caused the pulse to drop from 88 to 62, a loss of 26 beats. The pressure on the eyeballs never seemed to do any harm. It exaggerates bradycardia when it is of nervous origin, and may exaggerate arhythmia. With rudimentary exophthalmic goiter and very emotional subjects, with a tendency to "hot flashes" and profuse sweating, pressure on the eyeballs is liable to accelerate the pulse.

War.—From a letter just received from an eye-witness of conditions in the hospitals and among the sick and wounded prisoners in one city in the Balkan Peninsula, the following paragraph is taken: "Coming to the hospital, we found three flights of stairs and landings crowded with some hundred sick and dying on the steps and floors, two rooms with forty beds tightly packed in each, with sick lying in the beds and others sitting on the corners waiting for some to die for their places—calling for water, and no water; calling for help, and no help—all in a state of the most horrible filth, walls and floors likewise, dysentery, typhus, wounds, meningitis, and diseases unknown to me—some puffed out near to bursting, others absolute skeletons; flies, lice and fleas, vermin swarming; one doctor, just arrived, striving to examine the sick, and a few frightened men trying to act as nurses, but needing rather to be nursed themselves. A few drinking-cups in common for all, filthy rags of clothes, and in many cases no blankets; a few sheets, drenched in filth, and death gurgles continuous."—*Am. Red Cross Mag.*, October, 1913.

Race Mixtures.—Dr. Eliot of Harvard spoke recently of the changes immigration has caused. In his youth Dr. Eliot's community was homogeneous. His father's servants, the men who worked his farm, the mechanics, all the servants at Harvard, were Americans, descended from Pilgrim stock. But those Puritans, let us remember, were themselves not at all pure ethnically. There has probably never been since Homer, nor for many thousands of years before him, a pure race of men. The English who supplanted the aboriginal Indians were by no means a pure type; nor were the Dutch, nor the French, nor the Spaniards. Take the Frenchman of to-day. In the North are the descendants of the Belgae, the Walloons and other Kymri; in the East those of Germans and Burgundians; in the West Normans; in the center Celts, who in the epoch when their name arose consisted of foreigners of various origins and of the aborigines; in the South, ancient Aquitanians and Basques. Professor Boas of Columbia has found that where the ratio of race-intermingling is as one to nine there will be, among the more numerous population, only eighteen per thousand in the fourth generation of pure blood; and where two types intermarry with equal freedom, less than one person in ten thousand will be of pure descent—that is, within a century the process of intermixture should be complete.—*Harper's Weekly*, Feb. 7, 1914.

Medicolegal

Liability of Employer for Death of Employee when Anesthetic is Administered by Layman—Duty to Furnish Two Physicians—A Physician Deemed Iincompetent

(Nations vs. Ludington, Wells & Van Schaick Lumber Co. (La.), 63 So. R. 257)

The Supreme Court of Louisiana holds that an award of $8,000 damages should be increased to $10,000, or $5,000 for the widow and $5,000 for the children, for the death of an employee of the defendant whose hand was injured while he was at his work, and who died an hour or so later on the operating-table, while chloroform was being administered to him preparatory to an operation on the injured hand. The court says that the physician was assisted by his wife, who had graduated as a trained nurse, and by the saw-filer of the mill. The latter administered the chloroform. It seemed that it was he who usually performed that task on such occasions at that mill. The physician said that the patient had taken the chloroform and gone under complete anesthesia nicely, and that he had started to wash and clear up the hand, preparatory to the work, when he noticed that the patient had quit breathing, and he sought to restore respiration. The physician gave it as his opinion that the man died from nervous shock and the ordinary effect of chloroform. But the expert evidence showed that the man exhibited none of the symptoms of shock, and the court must conclude that his death was caused by the chloroform.

Was it negligence to allow a layman to administer it? The court does not think there can be any serious question but that allowing a layman to administer the chloroform was the taking of a very great risk, and constituted negligence if it was avoidable. As to that, nothing showed that it was not avoidable in the sense that, rather than take the risk of a layman administering the chloroform, it would have been better not to have performed the operation at all, but simply to assuage the pain by sedatives. But, granting that an operation was necessary, and that the anesthetization was advisable, nothing showed that it was not possible to secure an assistant physician. Half a dozen lived within a couple of miles, and the mashing of a hand, even though more aggravated than was shown to have been the case in the present instance, is not so liable to be promptly fatal as not to allow of time in which to summon a neighborly physician; and temporary relief from pain can be given without danger to life. It was said that an effort was made to summon one of the physicians of the town not two miles distant, but the evidence left no doubt that no serious effort was made, and that the saw-filer was supposed to be entirely competent in the premises.

The man was negligently dealt with. *On whom rested the responsibility? The attending physician* said he demanded an assistant of the assistant superintendent of the mill and of the man himself, but the man himself was in intense pain, and hardly in a position to advise with the physician as to what was, under the circumstances, the best course to pursue. *The responsibility* rested, the court thinks, on the assistant superintendent, who failed to procure an assistant physician, and on the physician who consented to proceed without competent assistance.

A condition of the employment contract at the defendant's mill was that the company should withhold weekly out of the wages of the employees a certain amount to go toward a fund for securing medical aid for the employees in case of need. The company itself contributed no part toward the fund and derived no profit therefrom, save perhaps in the betterment brought about thereby in its labor conditions. Beyond making this weekly contribution, the employees took no part in procuring the medical aid. The company retained that function in its own hands.

This was a business arrangement between the parties; and a part of the company's understanding was to use due care in providing the employee with a competent physician, or with two if need were. The Supreme Court of Missouri has held that the company in such a case must go beyond employing a competent physician; that it "must go further and competently treat the patient." But the weight of authority seems to be that when an employer derives no profit from the retention of the hospital fund from its employees, it is liable only for failure to exercise ordinary care to select, employ and retain a competent physician. This, however, means, of course, that if a case necessitates the services of two physicians, then that due care must be exercised in providing the two. In this case the company clearly failed in its duty to provide this second physician. No effort, or, if any, only a merely perfunctory one, seemed to have been made in that regard. The attending physician "demanded" of the assistant superintendent that it be done, and it was not done.

Furthermore, the attending physician himself was a mere *substitute* for the regular physician, who was off on a *month's* holiday. He was not a registered physician of the state. It was argued that this did not detract from his competency. No, but it added to the defendant's burden of proof in showing his competency; a prima facie case to the contrary having been made out by the result of his work. Except out of his own mouth not a word was in the record as to his competency. From his own testimony the court gathered that his nervous condition was then, or had recently been, such that he had had to give up for a time the practice of his profession at the place where he had last been located. From the fact testified to by him of his having repeatedly changed location, the court gathered that there must have been something detracting from his success. Everything considered, the court does not think this physician was such a one as the plaintiff's husband had the right to be furnished with under the agreement with the defendant company.

Liability of Vendors of Dyed Furs for Injuries to Health

(Gerkin v. Brown & Schler Co. (Mich.), 143 N. W. R. 48)

The Supreme Court of Michigan holds that it may be a question for the jury whether, under given circumstances, a wholesaler is not liable for injuries resulting to a purchaser from a retailer, from wearing a fur-lined coat with a dyed or blended collar which poisons his neck, face and hands, causing him great suffering, and seriously injuring his health. It is a common understanding and a reasonable presumption that a fur coat is a harmless thing, free from suspicion of hidden dangers to any one, and the testimony in this case showed that this is true in fact in all cases in which the fur is not artificially colored; but it was shown that, if the fur is dyed, in certain cases some coats are imminently dangerous to the health of some persons, when used for the purpose for which they are manufactured and sold.

When the fact is once established and demonstrated by experience that a certain commodity apparently harmless contains concealed dangers, and when distributed to the public through the channels of trade and used for the purposes for which it was made and sold is sure to cause suffering to, and injure the health of, some innocent purchaser, even though the percentage of those injured be not large, a duty arises to, and a responsibility rests on, the manufacturer and dealer with knowledge, to the extent, at least, of warning the ignorant consumer or user of the existence of the hidden danger. Failing to do so, the dealer, as well as the manufacturer, who has the knowledge and does not impart it, is liable to a subsequent ignorant purchaser, reasonably within contemplation of the parties to the original sale, for injuries sustained through such hidden dangers. This is by reason of the duty the dealer owes to the public generally, which includes all whom it may concern, to give notice of any concealed dangers in the commodity in which he traffics, and to exercise a reasonable precaution for the protection of others commensurate with the peril involved.

That the great majority of persons are safe from the particular danger concealed in the article sold, or that few injuries in fact result from its use, does not militate against this principle when the certain fact of imminent danger to a percentage is established. Many people are immune from the most virulent contagious diseases, and the percentage of injuries to those ignorantly using defective machinery or dangerous explosives, or unwholesome and dangerously adulterated foods, is small in proportion to the number who ignorantly or knowingly use them; but it could not be contended, for that reason, that the person knowingly renting a house or selling clothing which were infected with small-pox, or selling defective machinery, or tainted meats, or dangerous explosives, without warning, to one ignorant of the danger, and who was injured thereby, might escape liability.

Liability between County and Town for Expenses of Quarantine

(Board of Commissioners of Vance County v. Town of Henderson (N. C.), 79 S. E. R. 442)

The Supreme Court of North Carolina holds that the town was not liable for the amount, nor for any part thereof, paid by the county on account of the maintenance and care of persons afflicted with small-pox, while they were quarantined by the county, during an outbreak of small-pox in the county and town, which latter is in the county, in the years 1911 and 1912. If Section 4508 of the revisal of 1905 ever imposed any liability on a city without a quarantine officer, the legislature intended by Section 21 of Chapter 62 of the Acts of 1911 to establish a new rule of liability for the expenses of quarantining diseased persons and to require that they should be paid by the county which had a quarantine officer, unless the town in that county, in which the expenses were incurred, had appointed a quarantine officer and undertaken for itself, by a system of quarantine, to isolate or segregate persons having contagious and other diseases, which were mentioned in the act, within its corporate limits, or, if possible, to take charge and supervision of the patients at their respective homes.

There is no good reason why the town or city should be charged with the double burden of paying its full lawful share of the county taxes and also the expenses of quarantine within its limits, from which it receives no more benefit or advantage than other sections of the county. But if it is not satisfied with the county system of quarantine, or for any other reason it establishes one of its own, and thus chooses to regulate its own affairs in this respect, it is proper that it should bear the expense and not the county. It is not just that the county should pay the expenses of the city quarantine when it can have no part in fixing or controlling the amount to be incurred or in adopting regulations or methods for the economical administration of the law, and the same rule applies with equal force to the city, when entire control is in the hands of the county authorities.

That Section 21 of Chapter 62 of the Acts of 1911 was repealed by Section 9 of Chapter 181 of the Acts of 1913 was not important in this case, as the county paid the expenses for which it here sued in 1911 and 1912, before the passage of the act of 1913, which should be given prospective operation.

Physicians Entitled to Recover for Treatment of Injured Employee—Term of Service

(Gray v. Lumpkin and Thomas (Tex.), 159 S. W. R. 880)

The Court of Civil Appeals of Texas on this appeal of the defendant, Gray, affirms a judgment against him, in favor of Drs. Lumpkin and Thomas, the plaintiffs, for services rendered to an employee of the defendant Gray, who had his leg broken by a horse falling on it. The court says that an employer as a rule is not, in the absence of an agreement or some stipulation, under legal obligation to furnish medical attendance for an employee who falls sick or is injured while engaged in his duties. Here, however, the defendant at the time proposed to pay the bill for services, if certain physicians were employed. The question was whether Dr. Thomas, of the partnership of Lumpkin and Thomas, was one of the physicians named by the defendant. There was no question raised as to the reasonableness of the charges made for the services and none that the defendant did not authorize one Kerr to employ medical assistance. The only controversy was a quibble whether a letter written by the defendant and sent by Kerr was addressed to two or three physicians, that is, whether it was addressed to Drs. Walker and Johnston, or to Drs. Walker, Johnston, or Thomas. But when life is at stake, or great bodily suffering, demanding immediate relief, an exact adherence to the letter of instruction should not be demanded from the agent or from those dealing with him. Laws are doubtless enacted and should be administered for the welfare of humanity, and in a case of this kind the court feels that the services and skill of the plaintiffs should be compensated when secured under the circumstances here shown.

It appeared from the defendant's testimony that before the employee was discharged from treatment the defendant informed the plaintiffs that he would not pay them, as he had not employed them to treat the injured man. On this proposition the defendant requested the court to charge the jury that they could not allow the plaintiffs for anything after such denial of liability. He did not discharge the plaintiffs from the case, but denied that they were ever in his service. Had they quit the case it would, under the statement of the defendant then made, have amounted to an admission that they were never in his employment. The court does not think that there was error in refusing the requested charge. The jury having found that the plaintiffs were employed to treat the case, that employment continued while the case demanded their services or until they were discharged by the defendant. Where two or more persons enter into a contract of a continuing nature, one of them cannot, by his own act, discharge himself from liability and put an end to the contract, without the consent of the other, unless there is an express power of defeasance reserved in him. If the plaintiffs had undertaken to treat the case under an employment to do so, as found by the jury, they were legally bound to continue until the patient was in condition to be dismissed from further treatment.

Manslaughter in Death from Attempted Abortion

(State v. Harris (Kan.), 136 Pac. R. 264)

The Supreme Court of Kansas holds that an information, alleging the use of a certain instrument to procure the abortion or miscarriage of a woman pregnant with a vitalized embryo, not necessary or medically advised to be necessary to preserve her life, resulting in her death, charges a crime which would be murder at the common law and which is manslaughter in the first degree under Section 12 of the crimes act of Kansas. Although such instrument was used with the assent of the woman for the sole purpose of procuring an abortion or miscarriage, still such use and purpose being immoral, violative of the law of nature, deliberate in character, reckless of life, and necessarily attended with danger to the mother and likely seriously to injure her, if her death result, the common law will imply malice and hold the person so using such instrument guilty of her murder, regardless of whether she was pregnant with a quick child or with a vitalized embryo.

Society Proceedings

COMING MEETINGS

American Medical Association, Atlantic City, June 22-26.

Missouri Valley Medical Association, Lincoln, Neb., Mar. 26-27.

CHICAGO MEDICAL SOCIETY

Regular Meeting, held Jan. 7, 1914

The President, Dr. Charles P. Caldwell, in the Chair

Artificial Pneumothorax in the Treatment of Pulmonary Hemorrhage

Dr. Ethan A. Gray: Instead of the term "artificial pneumothorax," let us say "compression of the lung." Compression applied to a bleeding lung will, in most cases—not all—stop the hemorrhage. When the bleeding point is protected by adhesions against sufficient collapse of the lung substance, compression will not stop the bleeding. When the hemorrhage originates in a thick-walled cavity, the possibility of stopping it by compression is doubtful. In hemorrhagic cases, as well as in non-hemorrhagic cases, the production of a pneumothorax rests chiefly on one factor, a free pleural cavity. Without this there can be no lung compression. Hemorrhages occurring in pneumonoconiotics cannot be treated by lung compression, first, because of the consistency of the anthracotic lung, and, secondly, because of the danger of shutting off some of the already diminished and much-needed aerating lung tissue. Ordinarily, in producing artificial pneumothorax bilateral disease is a contra-indication; the same rule applies here. In far-advanced bilateral conditions, however, antecedent pleurisy with its adhesions has usually already settled the matter for us.

In cases of hemorrhage demanding operation, it is obvious that no great amount of time can be spent in preliminary study of the case. In the non-hemorrhagic cases it is well to have the patient under observation for several weeks until a general decision regarding the operation can be reached. Often a patient presents a bilateral condition which, *per se*, excludes operation. Within thirty days one lung, affected in lesser degree, perhaps, clears up, thus creating a proper condition for the collapse of the cavernous lung. Again, such marked improvement in the local and general condition may be observed after a period of rest that the operation becomes unnecessary, and therefore unjustifiable.

The most important step in the administration of nitrogen in lung compression is to determine the spot where a free pleural cavity may be found. Last spring I reported four cases of hemorrhage treated by compression of the lung. In these four, one patient died of bronchopneumonia, which developed at the time of or somewhat before the compression. Two have had no recurrence of hemorrhage. The fourth patient, after having had three fillings, had no further bleeding. He gained markedly in weight and strength until early in July, when he again began to bleed. The blood loss was large and flooded both lungs. The offending lung was immediately compressed, but bronchopneumonia developed and death occurred in a few days. The results in this case have led me to prolong the compression in subsequent cases. Since then I have used this method in six other cases, with no return of the hemorrhage in four, death from bronchopneumonia in one, and a checking of bleeding in one, with rapid decline.

Lung compression is indicated in severe pulmonary hemorrhage cases and should be made as soon as possible to forestall a fatal bronchopneumonia. It is of no avail once bronchopneumonia has become established. The lung should be kept in compression for at least four months. Aside from the value of compression of the lung as a hemorrhage agent, one cannot underestimate the influence of prolonged rest on the tuberculous process.

Treatment of Tuberculosis by Pneumothorax

Dr. John B. Murphy: There are many things to learn about tuberculosis. We are unsettled as to the location of the primary lesion. Is it a direct inspiratory infection? Is it primarily of gastro-intestinal admission? Is not the skin overlooked entirely as a means of admission of the bacilli into the circulation? All these questions are of prime importance in the management of tuberculosis, and should be settled. When the bacilli are admitted, how do we know that they are arrested? How do we know that a tuberculosis is present? Tubercle bacilli are a late manifestation—often a very late manifestation—of tuberculosis; but we are still in that stage at which the average man is satisfied if he can make a diagnosis on the finding of the tubercle bacillus. The diagnosis of tuberculosis must be made long before bacilli are present in the sputum. On the early diagnosis depends the result of treatment. What rôle can we play in aiding the repair or healing of that tuberculous process? How does repair take place, and what contributes to it? Repair or resistance to tuberculosis consists of (*a*) local and (*b*) constitutional resistance. Tuberculin is one agent we can use. I have been using it since it was introduced to the profession, first in large doses and then in small doses, and finally I came to the "individualization" dose. There is no average dose; there is no common dose; there is a dose for one individual and that individual alone. I become more enthusiastic over treatment by tuberculin every day.

In the local management of tuberculosis of the lung, compression of the lung by artificial pneumothorax is now the dominant treatment all over the world, because it places the diseased lung at rest. When shall we use this treatment? I was shocked a short time ago, in looking over the literature on pneumothorax as a treatment for pulmonary tuberculosis, to read that some of the ablest men suggested it as the treatment for tuberculosis when it had not yielded to other means. The old appendicitis proposition all over again. Why must we wait until there are cavities in the lung? Why must we wait until there are hemorrhages? Why must we wait until a whole lobe of a lung is involved? Use it now. Pneumothorax is a mechanical aid to Nature in the process of cicatrization and encapsulation of a tuberculous focus in the pulmonary tissue.

What are the changes which pneumothorax produces when properly and timely administered? It lowers the temperature rapidly by the rest which is given the focus of infection. It stops the expectoration rapidly. With the expectoration and the absorption stopped, of which the temperature elevation is a manifestation, the patient's general condition improves and he takes on weight. There are less likely to be recurrent hemorrhages.

DISCUSSION

Dr. John Ritter: We need social help in the treatment and cure of tuberculosis. The medical aspect alone will not help us out sufficiently to arrest the tuberculous process; consequently the social question must be taken into consideration. The old tuberculin is good when used for diagnostic purposes, but for therapy it should not be used. I use tuberculin quite extensively, and follow Wright's method. When I get to the point at which a patient is doing well, I remain there. The early diagnosis of tuberculosis as described in the text-books is misleading. When the text-book description is positive, the condition will long have passed the incipient stage. There is undoubtedly a so-called preincipient stage, before there are any physical findings in the chest. It is then that a diagnosis should be made.

Before we advocate the use of anything for the treatment of pulmonary hemorrhage, we must ascertain if the hemorrhage is really pulmonary. Pulmonary hemorrhage may be the initial sign of tuberculosis, or it may be the terminal stage of a pulmonary condition. I think that the percentage of cases that can be treated with pneumothorax is very small. Then, again, the percentage of patients who will retain gas—into whom we can get the gas—is very small. The percentage of those that are really benefited, producing arrest in the process, is again small, so that the percentage of patients that are really benefited by the treatment is meager. It will never be a means of treatment in a great many cases of pulmonary tuberculosis.

DR. CLARENCE L. WHEATON: The induction of artificial pneumothorax is an epoch in the history of tuberculosis. I regard it as a discovery of as great practical value as the discovery of the specific organism. The cessation of hemorrhage and of cough, the diminution of temperature and the general sense of well being mark practically all of these cases. If we can succeed in obtaining a serum possessing antitoxin properties which might neutralize even slightly some of the secondary phenomena of tuberculous infection we shall be near the goal of the greatest scientific achievement.

DR. W. B. METCALF: We have not fully appreciated the value of tuberculin as a diagnostic agent, and we have been slow to recognize the value of artificial pneumothorax as an agent in the treatment of tuberculosis. I should like to ask Dr. Murphy if, in cases in which both lungs are infected, he would think it a good plan to inject first one side, and after a period of time the other side? Injection of normal salt solution into the pleural sinus in cases in which there have been recent adhesions has been advocated by some authorities, for the purpose of opening the pleura sufficiently to allow the inflation with nitrogen. I should like to know if Dr. Murphy thinks this is a good policy.

DR. ETHAN A. GRAY: I do not consider that the percentage of cases to be treated by pneumothorax is limited. If you wait a long time, it is limited, but it is not right to wait. I think that Dr. Murphy put it very well—it is the old appendicitis proposition over again. I prefer to make my diagnosis, if I can, long before I find the bacilli.

DR. JOHN B. MURPHY: I have had only a small number of bilateral cases, and I am not in a position to give an opinion on the value of the treatment in these cases. In my original paper I suggested that it be used in the single lobe cases. I was taken to task, however, for that, and it was said that the bilateral cases did remarkably well. Therefore I feel that the opinion of men who have had a larger number of these cases should be accepted rather than mine.

NEW YORK ACADEMY OF MEDICINE

Meeting held Jan. 15, 1914

The President, DR. WILLIAM H. POLK, in the Chair

Intestinal Stasis

DR. JAMES T. CASE, Battle Creek, Mich.: In every instance in which roentgenoscopy has been made following a short circuiting operation, I have observed retrograde peristalsis in the colon. In many of these cases there was also a reflux of colonic contents through the anastomotic opening into the small intestine, and the resulting stasis converted the terminal ileum into a veritable colon of indefinite length. In some cases the terminal ileum was found to have a caliber of the colon itself, so that it was not easy to differentiate ileum from colon. There is another class of cases in which ileal stasis has existed and no adhesions have been found. A study of these cases leads to the conclusion that a large proportion of ileal stasis is due, not to kinking or adhesions of the terminal ileum, but to incompetency of the ileocolic valve, or to spasm of the ileocecal sphincteric mechanism, or to a combination of these two factors. Certain striking cases have supported the idea that normal ileal stasis is increased in all conditions leading to spasm, probably most marked in acute appendicitis, and less marked in chronic appendicitis. My observations give confirmation to the belief that the normal ileocecal valve is thoroughly competent. Without exception, when the ileocecal valve has been found incompetent to the enema on one occasion, it has been found incompetent at all subsequent observations. In more than fifty cases we have definitely proved the regurgitation of ingested bismuth from the colon back into the ileum, no new bismuth meal having been taken in the interim. In every instance in which the ileocecal valve proved incompetent to the enema, at operation the surgeon found gas or fluid distention of the terminal ileum in spite of thorough efforts at preoperative bowel cleansing. The incompetency has been cured in a number of cases by a simple surgical procedure, consisting in the placing of several sutures in such a manner as to restore the invagination of the bowel without narrowing its lumen. The operation is practically bloodless, does not involve opening the peritoneum, and is quickly accomplished.

Roentgenoscopy in Gastric and Duodenal Diagnosis

DR. ARIAL W. GEORGE, Boston: The greatest value in the Roentgen diagnosis of gastro-intestinal diseases is the possibility of classifying the cases into medical and surgical. If one relies on the Roentgen-ray evidence alone a considerable number of acute, simple peptic ulcers will be overlooked. I am convinced that six hour gastric stasis is the least important factor in Roentgen bismuth diagnosis. The presence of gastric spasm is one of the most potent sources with which one has to contend; it may be due to gastric or duodenal ulcer, gall-bladder disease, appendicitis, renal calculus, diseases of the nervous system, chronic morphin and nicotin intoxications, the vague clinical symptom complex known as vagotonus, and other causes. The positive diagnosis of acute, simple, peptic ulcer is frequently impossible. With chronic gastric ulcers the situation is different; here there is the presence of scar tissue, or considerable erosion and penetration, and the bismuth line shows excrescences, outpocketings, niches and hour-glass contractions. Usually repeated examinations will clear up the diagnosis. The evidence of perigastric adhesions is usually best obtained by fluoroscopic examinations, and this method is of value in chronic ulcers in the cardiac or median portions of the stomach. By means of plates taken in the lateral position, views may be obtained of the anterior and posterior walls of the stomach, and a lesion detected that cannot be observed in any other way.

As yet we have failed to find a single case of gumma of the stomach. Cancer patients are often made so comfortable by medical means, under a mistaken diagnosis, that they easily pass far beyond the operative stage. We must try to make a diagnosis of cancer before one can be made by clinical methods, if the patient is to have the advantage of early and radical operation. In the bismuth Roentgen method we have a positive aid, especially in that large number of cases in which the carcinoma is situated in the fundus of the stomach. It is possible to demonstrate on the negative a cancer as small as an average ulcer would be. The normal condition of the duodenum can be detected in every normal individual and the presence on the plate of a constant defect in the cap of the duodenum means a real pathologic condition. No patient with duodenal ulcer should be operated on unless the bismuth examination shows a definite, constant deformity of the "bishop's cap." In this connection the negative diagnosis is as valuable as the positive; every patient in whom a normal duodenal cap can be demonstrated has no indurated or surgical ulcer of the first portion of the duodenum. Adhesions resulting from repeated infections of the gall-bladder can frequently be detected by their attachments to the antrum of the stomach, the first or second portions of the duodenum, the hepatic flexure or the transverse colon. Occasionally, but not often, the shadow of an enlarged bladder can be seen, but not often enough to warrant a positive diagnosis.

DISCUSSION

DR. WILLIAM H. STEWART: It seems to me that the end of exploratory laparotomy is at hand. The Roentgen diagnosis is only one of the means toward reaching conclusions. It should always be combined with the clinical findings and laboratory reports; this is particularly true of diseases of the gastro-intestinal tract. While I believe in the direct positive method in acute peptic ulcers, or erosions of the stomach, one must be guided by the symptom complex if one hopes to make a correct diagnosis; in chronic ulcerations one is not confronted by difficulties so great, since here one can obtain direct ocular evidence. Too much importance cannot be laid on the necessity for the earlier use of the Roentgen ray in the diagnosis of carcinoma. Hypermotility, when not caused by carcinoma of the fundus, or achylia gastrica, or chronic gastritis, associated with actual persistent deformities in the bulbus duodeni, make the diagnosis comparatively easy and should be more readily taken advantage of by clinicians in any questionable case.

There seems to be considerable difference of opinion as to when ileal stasis is present. Some writers assert that no case is one of ileal stasis unless the bismuth meal is retained in the ileum at least twenty-four hours. It is my belief, however, that no hard-and-fast rule can be made, as it depends in a great measure on the amount of obstruction. As a matter of fact, the important point to be cleared up is what is causing the retention. Chronic appendicitis with accompanying adhesions is, in my experience, the most common cause of ileal stasis. Competent roentgenologists have now reached the goal where they can demonstrate a patent appendix and ascertain whether or not these accompanying adhesions are causing an obstruction of the ileum.

Dr. Lewis Gregory Cole: In 1903 I detected my first case of ileocecal insufficiency, and I believe that this is the greatest cause of ileal stasis.

Dr. Albert Charles Geyser: I have not been convinced of the seriousness of insufficiency of the ileocecal valve. The very fact that 10 per cent. of all valves examined are defective leads one to take rather an optimistic view of it. Other things being equal, I can see a conservativeness in such a weakness, and it may act occasionally as a real safety-valve.

Dr. Anthony Bassler: The point made by Dr. Case that these kinks and bands but rarely have to do with actual stasis, is an important one for surgeons to remember. In my experience the so-called ileal kinks are a most common finding and yet they but seldom cause stasis mechanically. To the theory of ileal stasis being caused by incompetency of the ileocecal valve, I would add that of primary toxemia in the alimentary canal, wherein the stasis is caused by degeneration in the sympathetic nerves and ganglionic cells. In this way the nerve balance of tonus is interfered with so that deficient motility and some degree of dilatation with attenuation of the intestine is responsible for the delay in transit of its contents. I believe that one cannot make a diagnosis of gastric or duodenal ulcer along such lines as rapid emptying of the stomach, reverse peristalsis, etc. The safe way of diagnosing these conditions is along the lines of pitting, diverticula or filling defects. Recently a well-known roentgenologist and a serious worker featured the diagnosis of gastric and duodenal ulcer along the lines of stasis in the stomach. In 120 cases of proved duodenal ulcer, stasis was observed by me in thirty-five, making 28 per cent. From the Mayo clinic, Dr. Eusterman has just reported 776 cases of duodenal ulcer, also proved by operation, with stasis present in only 26 per cent. In my experience, stasis is present in gastric ulcer in 34 per cent., whereas in 324 cases in the Mayo clinic it was present in only 29 per cent. It is important to state that in the cases in the Mayo clinic and in my own the diagnosis of stasis was made by the test meals, the only sure way of doing it. Therefore, one set of men feature the diagnosis on the basis of rapid exiting, and another by delay in exit, whereas the truth is that neither one is characteristic of ulcer, although either one may be present.

NATIONAL CONFERENCE ON RACE BETTERMENT

Held at Battle Creek, Mich., Jan. 8-12, 1914

(Continued from page 484)

The New Human Race

Dr. J. H. Kellogg, Battle Creek, Mich.: Man has improved every useful creature and every useful plant with which he has come in contact, with the exception of his own species. Why talk about a new race when the average length of human life has doubled within a couple of centuries, and when greater progress in the arts and sciences has been made within a century than within all the previous centuries of human history? The upward trend relates exclusively to art, science, ethics and other matters pertaining to the intellectual and social life of the race. Racial and national pride naturally lead us to believe that the race is advancing.

The fact that the average length of human life has more than doubled in the last two hundred years has been accepted as conclusive evidence that the vital stamina of the race is improving. Notwithstanding, this progress may be more apparent than real and permanent. Our birth-rate is steadily declining. Of twenty million schoolchildren in this country not less than 75 per cent. need attention for physical defects which are prejudicial to health. Insanity and idiocy are increasing. Diseases of vice, the most insidious enemy of this and future generations, are spreading rapidly, according to medical men. We have lacked the moral courage to recognize and fight this scourge. Alcohol and drug habits are constantly adding new victims. Suicides are increasing and now reach the enormous total of about 15,000 annually. The important organs of the body are wearing out too soon. The death-rate from the degenerative diseases of the heart, blood-vessels and kidneys, including apoplexy, has increased over 100 per cent. since 1880. These diseases claim over 350,000 lives annually. Fully 60 per cent. of these deaths are preventable or postponable, if the disease is discovered in time. Periodic health examination would detect these chronic diseases in time to check or cure them. The annual loss from pneumonia aggregates 135,000 lives, a large portion of which is due to weakened bodily resistance from degenerative affections. Cancer claims 75,000 lives annually, and is increasing. Pellagra is increasing rapidly in our Southern states. Over 150,000 Americans are destroyed annually by tuberculosis. We know how to prevent it, but our taxpayers object to the expense and leave the battle almost wholly to charity. Over 25,000 Americans are still sacrificed to the preventable filth disease, typhoid fever.

Opinions are divided as to the causes of race degeneracy. There are two great causes, heredity and environment. It may be impossible to say which is the more active. The results of recent researches, however, seem to indicate that the influence of environment may be much greater than some have supposed. The blighting influence of syphilis, alcohol, tobacco and other drugs, gluttony, sensuality and other vices cannot be questioned. We need not return to savagery to be healthy, but we must see that the air we breathe is clean, that the food we eat is wholesome and that the water we drink is pure. We must cultivate clean blood instead of blue blood. Society must establish laws and sanctions which will check the multiplication of the unfit. Eugenics and euthenics must become dominant matters of study and concern. The beginnings of chronic diseases should be detected and arrested.

Every board of health and official health agency should be actively engaged in the battle against disease and degeneracy. This work should not be left to individual initiative. The establishment of a national department of health will provide a central bureau by which to unify the work.

Some Efficient Causes of Crime

R. B. von Kleinsmid, Jeffersonville, Ind.: The conflicting conclusions heretofore reached in criminology are: 1. To a greater or less extent, every man is guilty of crimes, and his detection, conviction and sentence avoided only because of concomitant circumstances. 2. All criminals are vicious men, and consequently it is the duty of society to hunt them out, wherever they may be found, in order to mete out to them that degree of punishment appointed by legislation for the particular crime committed. 3. Transgressors of the law would be few, if any, except for a peculiar and contaminating social environment. 4. All criminals are defectives; no man of normal mental and physical status commits a crime. Until recently criminology was regarded as a legal science exclusively. Now there are indications that there are many who believe it to be purely a social science. Then there are those who insist that it has its origin in medicine and psychology.

Any one who has labored among those convicted of crime is impressed with the fact that they are beings of retrograde type. Responsibility for crime in the manifestly subnormal is quite out of the question; these will always be mere children and require a guardian. Crime is more than a mere accompaniment of defective mind. It is the natural outgrowth of faulty mental processes. This doubtless accounts for the fact that punishment cannot cure the criminal or even deter others from committing crimes. Treatment, not punishment, is needed.

Sterilization

MR. H. M. LAUGHLIN, Cold Spring Harbor, N. Y.: There are two sides to the problem of the treatment of criminals—the constructive, which has to do with the bettering of the two levels of humanity, and the negative, which has to do with cutting off the degenerate ones. Many remedies have been proposed for effecting the betterment of humanity by eliminating its lower levels. Segregation alone is not sufficient, and sterilization must come to its aid.

Uncinariasis

DR. LILLIAN SOUTH, Bowling Green, Ky.: The hookworm is found in every country in the world which lies between 30° north and 36° south latitude. Hookworm disease simulates consumption, and often these patients are treated for tuberculosis for years. Kentucky ranks first in the tuberculosis rate because we have so much hookworm disease which is mistaken for tuberculosis. Infection with this disease also retards development, a child of 15 or 16 not reaching the physical development beyond that usually expected in a child of 12. Some cases of pellagra were entirely cured when the patients were relieved of the hookworm. The peculiar skin eruption is one of the symptoms of hookworm disease. Whether there is any connection between the two diseases of pellagra and hookworm is not known, and these cases may have been wrongly diagnosed as pellagra.

Kentucky is spending five millions a year for the education of the children, but the children cannot go to school because of hookworm disease. There are not enough able-bodied men in some of the towns in Kentucky to hold the offices. Hookworm disease is not alone a disease of the poor. The whole thing, in the matter of prevention, is a question of a sanitary water-closet system. The State Board of Health of Kentucky has devised a sanitary water-closet with separate tank arrangement, built of cement, which is fire-proof and does not need to be cleaned out. By the use of these sanitary water-closets it is expected that we shall revolutionize the whole South in combating this disease.

Function of Individual, City, State and Nation in Bringing About Race Betterment

DR. W. A. EVANS, Chicago: 'The individual can contribute toward race betterment by keeping his body in better condition, and by caring for a better machine than is the present average machine. By bringing up the average of capacity in the human machine we shall bring up the average of undertaking by the human machine. We are fairly well equipped for the ordinary work of every day, but the average man is totally unequipped when called on to do work outside of that usual routine—any extraordinary or unusual thing. Therefore, my first suggestion is that the individual shall contribute to the movement for race betterment by maturing and maintaining a better machine than the average, as it at present prevails. My second suggestion is that those who constitute this audience, and that greater audience to which the arms of this audience will in time extend, enlist themselves in those eugenic movements that have as their object the correcting of these errors at the point of origin. It has been suggested that a part of this movement is corrective in character—that a part of it has to do with that part of society which is distinctly antisocial, and that measures for control must be legislative in activity, must be administered by government, and must be corrective in character. It was suggested that there is another side to this question, and that is the side of positive eugenics. My suggestion is that you lend your support to this side as well as to the other side.

The constitution of the United States twice refers to the activities of the government in behalf of the welfare of the people. Those references are in the same articles of the constitution in which there is given power to the national government to protect its people against armed invasion. It is there specified that the government shall have the right to maintain armies and navies and do such other acts as are necessary for the protection and the welfare of the people. In the first of these references the inference clearly is that the legislators had in mind acts for the protection of the people against invasion from without. In the second reference there is a broader authority, and it is evident that those who were conferring that authority had something else in mind. In this country we have a machine for the care of those who have developed disease. There are two hundred thousand men and women who are engaged in that work. About a hundred and fifty thousand of them are fairly well trained, technically trained, in the work that they are carrying on. Then there are at least fifty thousand others who are more or less broadly trained, who are doing the work of parts of this curative machine. But we need something more, and that is the machine for doing the work of personal hygiene.

My criticism of the work of city, state and national health agencies is that they are in reality departments of ill health, and they contribute but indirectly to the question of health, to the promotion of human efficiency. They contribute but indirectly to race betterment. They contribute but indirectly to the purifying of the stream. My suggestion is that they gain something more of vision; that they broaden out, and that they see man in the large; that they see society in the large.

MISS M. E. BINGHAM, Rochester N. Y.: Rochester has just adopted a new point of view regarding municipal responsibility. Premature death, unnecessary inefficiency and sickness are due to ignorance. It is the function of the city to place within the reach of every person the necessary knowledge. People have derived their knowledge about these things in a haphazard way, from hearsay, from newspapers and magazines. In Rochester the Woman's Educational and Industrial Union sent a petition signed by three thousand taxpayers to the board of education, asking that instruction be given in physiology, hygiene, nursing, dietetics and things of that description, and the board of education has agreed to do this. There will be a course extending over twelve weeks, two lessons of one hour each a week, one by a doctor, and one by a nurse, and in this course there will be taught physiology, the care of the child, hygiene, psychology of adolescence, first aid, emergency work, causes of disease, prevention and research of disease, rational principles in the care of disease, household and civic hygiene, and motherhood. If the women of Rochester appreciate this course by attending, the work is to be enlarged.

History of the National Board of Health

DR. STEPHEN SMITH, New York: The idea of a national board of health began as early as 1866, in the American Public Health Association. The idea naturally grew of having not only a municipal authority and a state authority, but also a national authority. The first suggestion was made by the health officer of the city of Washington, who was prominent in the first movement to organize a national board of health. The first obstacle was the states' rights idea. There was a disposition on the part of the members of Congress to oppose the creation of a board of health that would interfere with the state and municipal authorities. Their conception of the board was altogether wrong in that respect. It was not intended to interfere with the affairs of the states and cities any further than the national government now interferes.

Not much headway was made for several years, but when the great epidemic of yellow fever in 1878 made its appearance, and its devastations were so great that neither municipal boards nor state boards of the South could control it, there was a call for general aid, not from the government, but from voluntary organizations. A Mrs. Thompson of New York contributed a very large sum to what was then known as the Marine-Hospital Service, the head of which at that time was Dr. Woodworth. This fund was used to relieve distress and promote efforts to control the epidemic. A commission was sent south after the epidemic had subsided to study the question of yellow fever and its prevention. Mrs. Thompson provided that the commission should find the cause, if possible. The idea developed that there was need of more thorough quarantine in preventing the admission of yellow fever.

The first bill was introduced into Congress in 1879. I drew the bill after the plan of the Department of Agriculture, which was then comparatively new. It fitted exactly the ideal that we had of what a national board should be. We wanted a minister or secretary of health, who should be a member of the cabinet. We planned that the organization should take the form of the Department of Agriculture in the general work of promoting public health and coordinating, as far as possible, all of the energies of the country to prevent epidemics coming into the country. This bill was introduced into the Senate, but it went into the pigeonhole of some committee and never appeared again.

Toward the close of that epidemic the feeling in the South became very much changed in regard to a national organization. They found that they had to call on the country at large for help, and the question arose, Why should not the national government aid us in these extremities? The objection was that it would interfere with states' rights. This gradually subsided under the pressure of the epidemic and its devastations, and in 1879 opinion had become very strong that Congress should take some action. A bill was then drawn up that created a national board of health, but it was drawn in such a way as to be of temporary effect. It was rather a board for investigating the question why there should be a board of health, why should there not be a national department of health. It had some powers of investigation, and it had an appropriation of $50,000 for temporary work. When the question came to vote, it was voted that even this organization should not be allowed to continue more than four years. It was first limited to one year, but finally it was extended to allow it a lifetime of four years for its work.

It made a general investigation of our quarantines, and published a good deal of matter. At the same time the Marine-Hospital Service, headed by Dr. Woodworth, began to raise the question, Why should not the Marine-Hospital Service govern these quarantines? The Secretary of the Treasury, in 1880, recommended that the powers of the Marine-Hospital Service should be extended to include the quarantines. That was the first inroad that was made in favor of a national authority governing quarantines, and it has gone so far that they are now largely under the management of the United States Public Health Service. After the first year the fear of yellow fever subsided, and the old objections began to be revived. In 1882 the question arose as to the funds that were being used by the national board, Why should that not be turned over to the Marine-Hospital Service, that was now doing a good deal of sanitary work? Under the direction of President Arthur it was turned over to the Marine-Hospital Service. This deprived the national board of all means of doing anything; it had the authority to investigate, but no means to carry on investigation, and practically that was the end of the national board. I do not know that that law has ever been repealed; but it remained a national board for years without any power to do anything, and finally lapsed from mere lack of efficiency or ability to do anything. That is the history of the early movements to have a national board of health.

The National Department of Health

DR. HENRY B. FAVILL, Chicago: The American Medical Association has a central council known as the Council on Health and Public Instruction. My official relation to that Council has led to the invitation to me to present this subject. I shall not go into an elaborate argument as to the need of a national department of health. We are all convinced of that. I shall not talk about the details of construction or organization. Those are matters of detail. I am here to present to this conference a statement as to the status of the matter, as to what has been done and what is being done, and what, so far as we know, the prospects are. In the last few years this subject has received attention in a way that would lead one not familiar with the facts to suppose that it was a new proposition. The first mention of a plan of organization of a board of health appeared in the proceedings of the American Medical Association in 1871, following shortly after the organization of state boards of health in Massachusetts and California. The proposal first took the form of a voluntary council made up of representatives from the various state boards of health. The following year a resolution was adopted by the American Medical Association, asking Congress to establish a national sanitary bureau. In 1873, the President of the American Medical Association stated that a bill for this purpose had recently been introduced into Congress.

In 1874 the question was discussed by the American Medical Association under the title of "Waste of Life," a mere variation from our modern title of conservation of life, in which the subjects which would now be regarded as coming under the conservation idea were considered and the organization of state and national departments of health was urged. During the following year the discussion went on, culminating in the establishment of a national board of health in 1879, the duty of which was to report to Congress a plan for a national health organization. This board did not get anywhere and went out of existence through the failure of Congress to make an appropriation, because the appropriation had been diverted into other channels.

In 1886 a bill was introduced in the House of Representatives providing for a bureau of health. In 1891 a bill was introduced in the lower house providing for a department of health in the Marine-Hospital Service. In 1892 a bill was introduced in the House of Representatives. In 1897 the Springer bill was introduced in the Senate. None of these bills went farther than the committee stage.

In 1907, in the session of the American Medical Association, the Committee on Medical Legislation reported that the preliminary draft of a bill creating a national department of health had been drawn up by Dr. Barchfield of Pennsylvania, that the American Association for the Advancement of Science had created a committee of one hundred to consider methods for establishing a national department of health, and that this draft had been turned over to Professor Fisher, in order that it might be redrafted by some legal member of the committee. It was voted that the details of the plan be left to the Committee of One Hundred, to which the association pledged its support.

From this time on the effort of the American Medical Association has not exactly merged, but has been strongly coordinated with the efforts of a civic nature, of which Professor Fisher has been the exponent. There was no further agitation on the subject until Feb. 10, 1910, when the first Owen bill was introduced in the Senate, providing for a department of public health under a secretary of public health. This bill assembled the different bureaus in the government instead of creating a new department. It was given jurisdiction over all things relating to human and animal life. It was referred to the Senate Committee on Public Health and National Quarantine, before which it had a large number of hearings, but was never reported on, and died in committee with the expiration of the Sixty-First Congress.

I want to emphasize at this point that the American Medical Association from the beginning has been in favor of a Department of Health with a secretary in the cabinet. There was a time when, by reason of opposition, particularly in the time of President Roosevelt, who was positively opposed to a cabinet officer and to anything except a bureau of health, the American Medical Association agreed to anything which would be a beginning in this great movement. But that plan never having gone through, the general trend has been back again to the original idea of a Department of Health with a secretary of health in the cabinet. We are now standing for a Department of Health.

I feel justified in advancing the following propositions as generally accepted: 1. The necessity of some central federal health organization is agreed on by all those familiar with the situation. 2. While recognizing the paramount importance of state activity, owing to our existing form of government, the importance of federal activity cannot be overestimated. 3. The initiative of the present movement is largely due to the American Association for the Advancement of Science, in the organization of its committee of one hundred, which movement has been from the beginning supported and endorsed by the American Medical Association. 4. The American Medical Association is and always has been fully committed by its repeatedly expressed opinion and official reports to the support of a national Department of Health.

While the direct results secured by the efforts of the past forty years may not be entirely gratifying to the friends of this movement, the indirect or reflex effect of the continued agitation for better public health organization has been the stimulation of public health function, both federal and state.

Here is where we are to-day: Following the advent of the present administration and the calling of a special session of Congress last April, a conference was held in Washington, Monday, May 5, 1913, attended by the Council on Health and Public Instruction, the special committee on national health of the American Medical Association, and Professor Fisher, of the Committee of One Hundred of the American Association for the Advancement of Science. After protracted discussion, Professor Fisher formulated a program which was unanimously adopted, which included the following points: 1. A committee should be appointed to see President Wilson the next day, May 6 [which was done], and to communicate to him the result of the conference, requesting him *(a)* to decide on an administrative policy concerning public health legislation; *(b)* recommending that he definitely advocate the establishment of a Department of Health; *(c)* that he cooperate with us in securing a Committee on Public Health in the House of Representatives; *(d)* that he call a White House conference on public health similar to the Governor's Conference on Conservation; the object of this conference to be to promote the success of the President's policy, and if necessary to aid in framing that policy; *(e)* that at the next regular session the President send a special message favoring public health legislation, or else emphasize it in his regular annual message; *(f)* that the President select for the First Assistant Secretary of the Treasury some one interested in public health. 2. We should support the President in securing such public legislation as he decided to recommend.

I call your attention to the fact that the program adopted by the representatives of the American Medical Association and the American Association for the Advancement of Science pledged these two bodies to the support of such public health legislation as President Wilson might see fit to recommend at the next session of Congress. We are justified in believing that when this subject is next taken up in Congress it will be as an administrative measure. I call your attention to the degree to which we have put our interests in the hands of the administration. We have not only referred it to the administration, we have not only asked for a definition of policy, but without knowing what that definition of policy is going to be we have agreed to support that policy. Such a thing as that has hardly ever been done before; and yet I feel that we are perfectly safe in so doing. In the meantime, and in anticipation of such situations as may arise in the administration, the Council of the American Medical Association is going steadily forward in its campaign of public education on health issues, recognizing the fact that an active and intelligent public interest and support is of first necessity in securing the establishment of this department of health, for which the Association has steadfastly stood during its entire existence.

What the United States Public Health Service is Doing for Race Betterment

DR. H. W. AUSTIN, Detroit: I can only mention some of the work of the Public Health Service which relates to race betterment. Broadly speaking, all public health work promotes race betterment. Medical officers of the service are constantly making investigations as to the cause of unusual outbreaks of disease, publishing and distributing the results of their investigations and aiding the authorities in the state or municipality in which the disease occurs in its suppression or eradication. Examples of this are the pellagra investigations in several states, the prevention of malarial fever and hookworm, the investigations of the cause of the various outbreaks of typhoid fever and Rocky Mountain fever, etc. The government has also made extensive examinations of the waters of the Great Lakes and rivers of the United States to determine the amount and character of their pollution. The government is also making complete sanitary surveys of all dairy farms, including the production and transportation of the milk, and microscopic examination of the milk-supply of the large cities. Quarantine stations have been maintained at the large ports of entry by the service. Almost from the beginning of this government it has provided marine hospitals at the large ports of entry, where all American sailors could be cared for. The administration of these hospitals is one of the features of the service.

Some of the features of the service are closely allied to public health and eugenics. The service has established a tuberculosis sanatorium in New Mexico where patients from the United States marine hospitals are sent, and the results of this climatic treatment are most satisfactory.

At the hygienic laboratory in Washington a large number of medical officers are constantly engaged in scientific research work in preventive medicine. The morbidity and mortality statistics collected in various countries throughout the world are published in a bulletin that is distributed freely to all health departments and others interested in public health matters.

The prevention of the immigration of those who are diseased is a difficult but important function. The medical examination of five thousand immigrants in one day at Ellis Island, at New York, to determine whether there are any mentally or physically defective ones among them, is a most difficult task. It requires an expert alienist several weeks in many cases to determine whether a given patient is insane or not. The classification and sifting of those mentally weak is more important. This also requires much more time than is generally believed to be necessary, especially with those whose language and condition in life are entirely different from our own.

The Race Betterment Movement in Women's Colleges

DR. CAROLYN GEISEL, Rome, Ga.: If race betterment is to mean anything, it must begin with education for her who has to do with the race in its infancy. Does a college do it? There are two sorts of colleges in the United States, the coeducational institution, which gives to women the same kind of an education her brothers receive, and the other kind known as the finishing school, the female seminary. In these schools girls learn to dance, gibber French and German, read Greek, Latin and Italian, and paint on china, and do all this after the approved fashion. When she gets back from this school is she prepared for her holy place in life, her place in the world, which is the very root of all race betterment? She is not. Her body is broken. She gives her life, perhaps, for her first child, or else she lives and brings a weakling into the world which soon dies. One out of every two of all the children born dies before fully matured. I have for years cried out for a college that should teach women their own business. In Rome we established a chair of health and home economics in the college for women there, and since then two others have started the movement. One of the objects of this chair is to establish the young woman who comes there in health, so fixed and so definite, and so real, that when she is sent home she will not be the chief support of the doctor. This is accomplished by correcting the diet, by encouraging outdoor life, with physical exercise, and by regulating the dress. We see to it that the habit of self-drugging which prevails so much among the young women in colleges is put away, and do it by the efforts and offices of a resident physician.

It is a woman's business to do what God called her to do—and God called her to motherhood. Teach her to care for her health, and she will bring healthy children into the world.

2. **Pericolic Membranous Films and Bands.**—It seems to Pilcher as if sufficient clinical observation had now been accumulated to confirm and emphasize the teaching that right-sided pericolic membraniform veils and bands, crippling the peristaltic function of the cecum and ascending colon, are of frequent occurrence, and that when present they form a well-defined surgical condition which always is a menace as to the future, and in many cases has already become the cause of ill health and suffering. Whenever, therefore, the abdomen is opened for the relief of conditions involving right-sided symptoms, Pilcher advises that the operation should be so planned as to make it possible to explore for their presence and do whatever is necessary for their removal.

5. **Foreign Bodies within Tissues.**—In the method advocated by Brown a preliminary roentgenographic examination for the purpose of substantiating the diagnosis is made and the approximate position of the foreign body noted. The area of skin over the foreign body and a surrounding area of a few inches is then prepared in the following manner: Vertical and horizontal lines running at right angles to each other are painted on the skin with silver nitrate solution, thus laying the skin out into squares. The size of the squares can easily be made to bear a proper relation to the size of the foreign body on the one hand and that of the part to be prepared on the other. As a rule, one-inch squares will be found very convenient. The component lines of the checker board thus formed are numbered for the purpose of more easily locating the individual squares. The area thus painted should include one-half the circumference of the part. If the entire circumference is laid out in squares, the lines of one-half the circumference should be solid and those of the other half dotted. The silver solution is allowed to turn black and the skin thus stained. The lines are then painted over with white lead paint and this is allowed to dry.

Two roentgenograms are now taken, one, anteroposteriorly and one, laterally, to show the shadow of the foreign body with relation to the squares painted on the skin. By projecting imaginary lines from the shadow of the body in the two positions with relation to the outlying lines, its approximate depth from the surface is easily calculated. If the entire circumference of the part has been painted, the position of the body is noted accurately by projecting the point of intersection of the shadow with the solid line on one surface to its point of intersection with the dotted line on the opposite surface. If desired, a tracing of the lines and the shadow of the body may be made on a transparent paper and this tracing laid on the skin so that the lines of the squares correspond accurately. The shadow of the foreign body may then be marked on the skin with silver nitrate to be used as a guide at operation. Following the roentgenoscopy the white lead is removed and the part placed at rest until operation.

6. **Pneumococcic Arthritis.**—Bulkley cites one personal case and analyzes 172 cases collected from the literature.

7. **Prevention of Peritoneal Adhesions.**—Seventeen different substances and combinations were used by Pope experimentally to determine their value in the prevention of postoperative abdominal adhesions. It was apparent from the first that citrate of soda—2 per cent.—with hypertonic salt solution—3 per cent.—was the best medium used. It was found that hypertonic solutions remained longer in the abdomen than normal solutions. A hypertonic solution colored with methylene blue gave traces of its presence after forty-eight hours, while normal solutions disappeared in half this time. Two experiments were tried in which citrate solutions were employed after voluntarily severing many small vessels of the intestinal subserosa. No evidence of hemorrhage was found at autopsy one week later. In peritoneal postoperative inflammation, the height of the storm is past in forty-eight hours. The solution is present when most needed. When the insulted, traumatized endothelium is pouring out plastic exudate, with a large content of fibrin ferment, it is met by the inhibitory action of citrate of soda.

To test the toxicity of citrates and oxalates five grains each in one-half ounce of salt solution were injected intravenously in two rabbits. It had no apparent effect on these animals. It is not assumed by Pope that citrate solutions will prevent adhesions where large denuded areas of the peritoneum are exposed. These, he says, should be treated by omental grafts or mesenteric plication. It is not suggested that large quantities of solution be left in the abdominal cavity, although in the absence of pus it probably is not detrimental to do so, but that the usual operating-room solutions of normal salt have added to them a 1 or 2 per cent. of citrate of soda.

14. **Duodenum Ulcer Following Operation.**—In an investigation of the results following operation by Mayo on 600 cases of ulcer of the stomach and duodenum in which the history subsequent to the operation was ascertained, Graham found that 81 per cent. were so relieved as to be considered cured and 10 per cent. were markedly benefited, that is, 91 per cent. were cured or improved, and 5 per cent. of the remainder were moderately improved. The results in the gastric group were not as good as in the duodenal by 3 or 4 per cent. In a small number of the cases there was a recurrence of the symptoms following relief of some weeks or months; a small number of such have been reoperated on by the Mayos. Also a small number in which the primary operation had been done elsewhere were reoperated.

Gastrojejunostomy was the method of choice in the larger number of cases of duodenal ulcers subjected to operation. If actual obstruction existed to the third and fourth degrees, gastrojejunostomy, when properly performed, gave almost certain relief. The greater the obstruction within the limits the better the results of gastrojejunostomy and the converse holds equally true that those cases with slight obstruction or without obstruction furnish the highest number of failures to cure.

Failure to cure and recurrences following operation are divided into two general groups: First, failure of the operation to relieve the stomach of its acid, irritating secretions and inadequate protection of the ulcer itself during the healing period. Second, recurrence of the ulcer following gastrojejunostomy was apparent rather than real, and had its origin in improper suturing in the gastrojejunostomy. This happened in some cases which were most favorable for gastrojejunostomy, even when obstruction to the third or fourth degree existed at the time of the primary operation. Secondary operation showed that there was no recurrence of the original ulcer, but that a new ulcer had formed at the site where the gastrojejunostomy was made, due to heavy silk or linen sutures hanging in the suture line.

26. **Streptococcus-Pneumococcus Transmutations.**—Altogether twenty one strains isolated originally as hemolytic streptococci from a wide range of sources, including erysipelas, scarlet fever, puerperal sepsis, arthritis, tonsillitis, cow's milk, etc., have in one way or another been converted into *S. viridans* by Rosenow; 3 into *S. viridans* and into typical pneumococci, and 1 into *S. mucosus* as well; 1 of these corresponding at one time to the streptococci from rheumatism. Seventeen strains which were isolated as *S. viridans* chiefly from the blood and tonsils in cases of chronic infectious endocarditis and 2 strains from cow's milk have been converted into pneumococci, and 2 of these into *S. mucosus* also; 10 have been made to take on cultural and morphologic characteristics of hemolytic streptococci, in 2 of which the pathogenic powers were shown to be those of hemolytic streptococci; 1 strain was converted into hemolytic streptococcus, into *S viridans,* and into a pneumococcus.

Eleven strains isolated as pneumococci from the sputum, blood and lung in pneumonia, and from empyema and Cole's strains I and II have been made to correspond to hemolytic streptococci; 7 took on the features of *S. viridans;* the streptococci from 3 of these strains by animal passage acquired all the essential features of the streptococci of rheumatism; 2 have been converted into hemolytic streptococcus, the streptococci of rheumatism, *S. viridans,* and back again into pneumococcus Five strains of *S. mucosus* have taken on the cultural features of hemolytic streptococci. Two of these were converted in to *S. viridans.* Five strains of the streptococcus of rheumatism have taken on the features of hemolytic streptococci, 2 of *S. viridans* and 4 have been converted into pneumococci The transformation of some of the strains has been found to be complete by every test known The details of this work are described fully.

29. **Antibody Formation in Typhoid.**—Moon concludes that the protective effect of antityphoid inoculation lasts for a longer period than two years, and that this effect is due not so much to the persistence of antibodies in the blood as to the promptness with which new antibodies are formed in the presence of typhoid proteins

30 **Etiology of Acute Rheumatism.**—Three types of cocci have been obtained by Rosenow from the joints in rheumatism The strains from five cases, in none of which were muscles involved, produced green on blood agar, formed long chains of diplococci and large clumps in broth; when injected into animals they produced a non destructive arthritis, pericarditis and endocarditis The diplococci were distinctly larger and more uniform in size than those of the *S. viridans* In six cases, all of which showed more or less muscular involvement in conjunction with arthritis, the organisms isolated produced a slight but hazy hemolysis on blood agar plates, formed short chains and diplococci in broth, and when injected intravenously in rabbits commonly produced arthritis, endocarditis, some pericarditis, a myositis, and often a most pronounced myocarditis They are the same size as hemolytic streptococci, but the diplococcus arrangement in the chains is more marked.

In three cases, none of which showed symptoms referable to the muscles, the organisms produced small, grayish colonies on blood agar plates without perceptibly affecting the medium They formed clumps of small micrococci and occasionally diplococci and short chains. One of these strains produced arthritis, endocarditis and pericarditis, but no muscle lesions

Rosenow is convinced that these results would seem to explain why different observers have named organisms like these "streptococcus," "diplococcus" or "micrococcus rheumaticus," depending on the particular type with which they happen to be working The virulence of all three types is of a low order. The third group seems to be the least virulent, the first group occupying a middle position, those from cases of muscular and articular rheumatism being the most virulent.

The muscle lesions have been produced in numerous rabbits, dogs and one monkey The character of the lesions was similar in all The affinity for joints, endocardium, and often also myocardium and muscles which characterizes these organisms when first isolated, tends to disappear on cultivation It may be restored by animal passage, and other strains of streptococci under certain conditions may be made to acquire the features of the strains from rheumatism.

Experimental evidence has been produced to show that probable lodgment of organisms in the fine capillaries of the iris occurs in rheumatic iritis. The lesions in the appendix, the diarrhea due to colitis, and the enlargement of the mesenteric lymph nodes observed commonly in animals after intravenous injections of these strains, as well as their isolation from the stool during rheumatism in man, indicate that the organisms may gain entrance through the lymph structures of the intestinal tract. The strains from muscular rheumatism, especially after one or two animal passages, as well as other streptococci when they have attained a similar grade of virulence, show a marked affinity for the mucous membrane of the stomach, the pelvic mucous membrane and medullary portion of the kidney and the gall bladder. Ulcer of the stomach, the picture of an "ascending" nephritis, cholecystitis with beginning formation of gall-stones, caused by streptococci, have been found repeatedly in rabbits and dogs injected with these strains, especially after one or more animal passages

32. **Cultivation of Virus of Vaccinia.**—Steinhardt and Lambert found that the virus of vaccinia incubated in tissue cultures composed of plasma and cornea from normal rabbits and guinea-pigs shows a definite increase, but the degree of multiplication is not comparable to that observed in cultures of rapidly growing bacteria There is no growth of the virus in preparations containing cornea killed by freezing or by hypotonic salt solution. There is no evidence of the growth of the virus in preparations in which pieces of heart, liver or kidney have been substituted for cornea. The virus is

14 **Duodenum Ulcer Following Operation**—In an investigation of the results following operation by Mayo on 600 cases of ulcer of the stomach and duodenum in which the history subsequent to the operation was ascertained, Graham found that 81 per cent were so relieved as to be considered cured and 10 per cent were markedly benefited, that is, 91 per cent were cured or improved, and 5 per cent of the remainder were moderately improved The results in the gastric group were not as good as in the duodenal by 3 or 4 per cent In a small number of the cases there was a recurrence of the symptoms following relief of some weeks or months, a small number of such have been reoperated on by the Mayos Also a small number in which the primary operation had been done elsewhere were reoperated

Gastrojejunostomy was the method of choice in the larger number of cases of duodenal ulcers subjected to operation If actual obstruction existed to the third and fourth degrees, gastrojejunostomy, when properly performed, gave almost certain relief The greater the obstruction within the limits the better the results of gastrojejunostomy and the converse holds equally true that those cases with slight obstruction or without obstruction furnish the highest number of failures to cure

Failure to cure and recurrences following operation are divided into two general groups First, failure of the operation to relieve the stomach of its acid, irritating secretions and inadequate protection of the ulcer itself during the healing period Second, recurrence of the ulcer following gastrojejunostomy was apparent rather than real, and had its origin year she had five or six attacks of cramps, but none severe enough to confine her to bed. Finally the cramps became rather severe and she was in bed all day previous to the time when the stone passed She had a constant desire to go to stool and her bowels would move slightly. Early the following morning, while at stool, she heard something very solid drop from her bowels and it proved to be a large stone The stone was 2 625 inches in length, 3 5 inches in circumference, and weighed 324 grams The center was composed almost entirely of pure crystalline cholesterin, while the several outer layers were of cholesterin and bilirubin calcium

111 **Urinary System and Female Pelvic Organs**—Realizing that lesions of the urinary system may occur either as complications or sequels of disease of the female organs the authors [illegible] the importance of determining their exact nature before resorting to an operation which otherwise may be inadequate or even unnecessary Experience in a large number of these cases has taught them that the solution of this problem cannot be gained from dependence on symptoms they can only serve as an indicator which points to the necessity of further investigations Whether it is primary lesion of the kidney or abnormalities of the pelvic organs which react on the bladder the subjective manifestations common to both are often limited to vesical symptoms The relationship of the one to the other can be determined definitely only by a thorough examination of the bladder ureters and kidneys A routine cystoscopic examination in all cases presenting vesical disturbances, irrespective of the coincident pelvic pathology should be the rule, for only by following this precaution can grave errors in diagnosis be avoided

112 Abstracted in THE JOURNAL, June 28, p 2065

113 **Postoperative Results of Trachelorrhaphy**—The presence of a marked endocervicitis is considered by Leonard as a contraindication to the performance of trachelorrhaphy He says that although serious postoperative hemorrhage is not infrequent after amputation of the cervix (5 per cent), this accident is very uncommon after trachelorrhaphy The influence of trachelorrhaphy in improving the general condition of the patient in properly selected cases quite as marked as that of amputation of the cervix In each instance about 90 per cent of the patients report improvement in the general health Although trachelorrhaphy may render a mild endocervicitis more amenable to treatment, it cannot be considered like amputation of the cervix, as a curative measure for this condition Laceration of the cervix is a frequent cause of dysmenorrhea in multiparae, and its removal by either amputation or the cervix or trachelorrhaphy is followed by the disappearance or amelioration of menstrual pain in over 60 per cent of cases Fertility is much more likely to follow trachelorrhaphy than amputation of the cervix

After amputation of the cervix, the incidence of abortion and premature delivery is greatly increased, while trachelorrhaphy has no effect on the course of subsequent pregnancy Labor after amputation of the cervix is usually difficult, while after trachelorrhaphy it is almost always normal Amputation of the cervix is an operation to be avoided in women in the child bearing period until all other therapeutic means have been exhausted Trachelorrhaphy has a therapeutic efficiency, in properly selected cases, quite as high as amputation of the cervix, and, having no influence on the subsequent marital history of the patient, is the operation of choice for women in the child bearing period

117 **Tumors of Nerves and Fibroma Molluscum.**—The tumor in this case involved the sciatic nerve and measured 6 inches in length by 3 in diameter and weighed 1 pound and 3 ounces

soon rendered inactive in preparations containing plasma and cornea obtained from an immune animal. The method of tissue cultivation is well adapted for the demonstration of immunity reactions *in vitro*.

35. **Septic Sore Throat Epidemic.**—In the two epidemics of septic sore throat which occurred simultaneously in May, 1913, in Cortland and Homer, N. Y., the two communities being three miles apart, the authors found that over 70 per cent. of the cases in each community occurred among the patrons of a dairyman, who was the only dairyman selling milk in both places, and who supplied less than 7 per cent. of the total milk-supply. Adjacent towns had no cases and, further, they received no milk from the suspected dairy. Physical examination of the cows and microscopic examination of milk sediments showed the existence of acute udder inflammation in two cows in the herd of the suspected dairyman.

Bacteriologic examination showed that cultures from the throats of four patients contained streptococci apparently identical with strains of streptococci obtained from the milk slime from the two cows suffering from garget. Cultures from the throats of eight other patients contained streptococci of this same type, but differing, by slight variations only, in their carbohydrate fermentations. The streptococci isolated from the milk slime from the two garget cows and the throats of four patients in the present epidemic correspond in all respects to strains of streptococci isolated previously from three cows of another herd known to be suffering from garget, and from the milk slime from one cow supposed to be normal, but which gave an abnormal amount of slime.

38. **Tubercle Bacilli in Blood.**—The entirely negative results obtained by Berry by the microscopic examination of fifty-one specimens of blood taken from patients in advanced stages of tuberculosis are in agreement with the experience of a large number of observers. Since organisms morphologically identified with tubercle bacilli are present occasionally in water and elsewhere it is fair to assume that some, at least, of the acid-fast bacilli observed in blood by different investigators were not tubercle bacilli, and where there are no confirmatory animal tests the proportion of specimens containing true tubercle bacilli must remain an open question.

39. **Arthritis Due to Friedländer Bacillus.**—On account of a history of chronic tonsillitis in Dick's case cultures were made from the tonsils. Colonies of *B. mucosus* (Friedländer bacillus) outnumbered all the other colonies on repeated examinations. Several varieties of streptococci were isolated and tested on rabbits in varying doses without producing joint lesions. When injected intravenously the Friedländer bacillus, on the other hand, produced joint lesions in rabbits and dogs in every instance. The organism was very toxic for rabbits. In six rabbits receiving from 1/10 to 1/5 of twenty-four cultures death occurred in from twenty-four to seventy-two hours, and in every case the bacilli were found in smear and cultures from the slight exudate in the joints of the animals, purulent pericarditis was found with bacilli present in the pus.

68. **Production of Gastric Ulcers.**—Steinharter investigated the possibility of producing ulcers by injecting clumped colon bacilli intravenously. An active strain of the organism in broth was agglutinated with weak solutions of acetic and hydrochloric acids. When 2 to 4 c.c. of such an emulsion was injected into the ear vein of rabbits the injection was almost uniformly followed by the formation of hemorrhagic gastric erosions or ulcers. The method employed was as follows: The agglutinating reagent, found to clump the strain of colon bacillus employed, was approximately a one-twelfth-normal hydrochloric acid solution. Twenty-four-hour-old broth cultures of the colon bacillus treated with this reagent in the proportion of 2½ c.c. of the broth culture to 1 c.c. of the reagent were incubated for twenty-four hours, and then centrifuged. The sediment was washed twice with normal salt solution and then shaken up with 10 c.c. of fresh saline. The turbid emulsion thus formed was injected intravenously into rabbits.

111. **Urinary System and Female Pelvic Organs.**—Realizing that lesions of the urinary system may occur either as complications or sequelae of disease of the female organs, the authors urge strongly the importance of determining their exact nature before resorting to an operation, which otherwise may be inadequate or even unnecessary. Experience in a large number of these cases has taught them that the solution of this problem cannot be gained from dependence on symptoms; they can only serve as an indicator which points to the necessity of further investigations. Whether it is primary disease of the kidney or abnormalities of the pelvic organs which encroach on the bladder, the subjective manifestations common to both are often limited to vesical symptoms. The relationship of the one to the other can be determined definitely only by a thorough examination of the bladder, ureter and kidneys. A routine cystoscopic examination in all cases presenting vesical disturbances, irrespective of the coincident pelvic pathology, should be the rule, for only by following this precaution can grave errors in diagnosis be avoided.

112. Abstracted in THE JOURNAL, June 28, p. 2065.

113. **Postoperative Results of Trachelorrhaphy.**—The presence of a marked endocervicitis is considered by Leonard as a contra-indication to the performance of trachelorrhaphy. He says that although serious postoperative hemorrhage is not infrequent after amputation of the cervix (5 per cent.), this accident is very uncommon after trachelorrhaphy. The influence of trachelorrhaphy in improving the general condition of the patient is, in properly selected cases, quite as marked as that of amputation of the cervix. In each instance about 90 per cent. of the patients report improvement in the general health. Although trachelorrhaphy may render a mild endocervicitis more amenable to treatment, it cannot be considered, like amputation of the cervix, as a curative measure for this condition. Laceration of the cervix is a frequent cause of dysmenorrhea in multiparae, and its removal by either amputation of the cervix or trachelorrhaphy is followed by the disappearance or amelioration of menstrual pain in over 60 per cent. of cases. Fertility is much more likely to follow trachelorrhaphy than amputation of the cervix.

After amputation of the cervix, the incidence of abortion and premature delivery is greatly increased, while trachelorrhaphy has no effect on the course of subsequent pregnancy. Labor after amputation of the cervix is usually difficult, while after trachelorrhaphy it is almost always normal. Amputation of the cervix is an operation to be avoided in women in the child-bearing period until all other therapeutic means have been exhausted. Trachelorrhaphy has a therapeutic efficiency, in properly selected cases, quite as high as amputation of the cervix, and, having no influence on the subsequent marital history of the patient, is the operation of choice for women in the child-bearing period.

116. Abstracted in THE JOURNAL, June 21, p. 2024.

117. **Tumors of Nerves and Fibroma Molluscum.**—The tumor in this case involved the sciatic nerve and measured 6 inches in length by 3 in diameter and weighed 1 pound and 3 ounces.

120 **Artificial Ureter Made from Abdominal Wall**—The following surgical procedure was carried out experimentally by Strauss An incision was carried from ½ inch below the angle of the twelfth rib in the midaxillary line downward to within 1 inch medianward of the anterior superior spine of the ilium. The muscles were divided down to the transversalis The internal oblique was divided and dissected back as far as its iliolumbar fascial attachment laterally and medianward to the belly of the rectus muscle A tongue shaped flap was now made, which included the transversalis muscle, fascia and peritoneum The peritoneum, fascia and muscle were closed with one suture starting at the superior angle of the pedicle of the flap, and while suturing the pedicle the sutures only penetrated the peritoneum and transversalis fascia The operation is now absolutely extraperitoneal

The ureter was exposed in the region of the flap and the ureteral arteries were tied with fine silk at both the distal and the proximal ends Two or three inches of the ureter were next resected A temporary ligature was placed on the proximal end of the ureter The lower free edge of the flap was picked up and the peritoneum and transversalis fascia separated from the transversalis muscle for about 0 5 cm An end to end anastomosis with the distal end of the ureter was made in such a way that the fascia and peritoneum were slightly within the ureter and the muscle without The proximal end of the ureter was placed on the upper portion of the flap and an end to end anastomosis made by a continuous circular suture Here, however, the peritoneum is not within the lumen of the ureter The edges of the flap were closed to complete the tube, using a continuous over and over suture going upward and crossing this with a suture downward, so as to make a figure X Fine arterial silk was used for the anastomosis and flap closure The temporary ligature was removed and the artificial ureter, as well as the ureter below the anastomosis became distended with urine and the rhythmic ureteral wave passed on over the ureter A fine rubber drain was left in the wound for the first few days to allow for the slight leakage of urine that might occur

At the end of seven months one of the dogs was anesthetized and opened The pedicle of the flap was normally intact The artificial ureter was shortened to about one third its original length so as to draw the ureteral ends nearer together The circumference and lumen of the tube were of the same size as when first constructed The tube as a whole felt hard and non compressible The peritoneum was adherent to it on one side and to the internal oblique on the other Many well defined blood vessels could be seen adjacent and in the adherent tissues The ureter was now divided 3 inches below the distal anastomosis and urine came through in jets in about normal quantity The specimen was removed and an opening made in the ureter about 1 inch above the proximal anastomosis A probe could be passed with ease through the artificial ureter and its anastomoses and also a second smaller probe could be passed alongside of it The hardened artificial ureter was opened with scissors It cut with difficulty Its inner surface appeared smooth and had the appearance of a lining membrane The body of the tube felt hard This, Strauss assumed to be due to infiltration of calcium and urinary salts The anastomoses showed no evidence of contraction or stenosis The kidney showed no changes

122 **Recurrences and Metastases from Cancer of Breast**—Fifteen cases are cited by Pfahler to show that the application of the Roentgen rays will at times cause a disappearance of both small and extensive areas of both recurrent and metastatic carcinoma, that the disease can at times be made to disappear when it covers the greater portion of the chest In at least one case there seemed to be produced some constitutional condition which led to the rapid disappearance of carcinomatous tissue that had not even been exposed to the rays The additional administration of thyroid extract in small doses seems to aid materially in the cure of the disease Pfahler advises that the disease should be treated as actively and with as large doses as circumstances will permit, using any possible means for the protection of the skin Since the above cases prove that extensive recurrent malignant disease can be made to disappear, the best time to treat with the rays is immediately after operation, when least disease is present This postoperative treatment should be thorough and given with the same care that would be used with palpable disease

125 **Hemostasis in Shoulder- and Hip-Joint Amputations**—A 4 inch roller bandage and an Esmarch rubber tourniquet is *all that* is needed by Norton for hemostasis The 4 inch bandage is made into a three or four ply strip 2 yards long and laid on the chest, extending over the shoulder, another similar strip is held over the scapula, the Esmarch tourniquet is applied over these two strips and pinned to each one with safety pins The strips are simply folded back and handed to the nurse, or can be tied under the opposite arm For hip joint amputation an anterior strip of bandage is placed so that the outer border of the bandage touches the anterior superior spine of ilium, and the posterior one is placed so that the inner border of the bandage touches the tuberosity of ischium Pull is exerted so as to keep the Esmarch snug in the crotch and in the groove below the anterior superior spine of the ilium The bandage pulleys are now passed over the shoulder of the other side and handed to the nurse, or, better still, tied securely

126 **Injuries of Abdominal Viscera**—The sign to which Claybrook first called attention in 1904 consists in the transmission of the heart and respiratory sounds, so that they can be heard all over the abdomen almost as well as over the chest The ear is all that is needed to elicit the symptom In the past nine years he looked for this sign, in all cases coming under his care, in which there was the slightest chance of an internal injury After following these cases up closely, he has come to the conclusion that the sign is, when present, a positive indication for immediate laparotomy, whether the other signs present indicate grave trouble or not It is present soon after the reception of the injury, and has been noted as early as a half hour after the reception of the injury It continues in unoperated cases as long as twenty four hours after injury and may last for days Claybrook believes that it is due to the irritation of the parietal peritoneum by the sudden outpouring of foreign material, as bowel content, blood and urine, into the abdominal cavity It is never present in cases of extraperitoneal rupture of the bladder, or in injuries of the abdominal wall, without internal injury He did not find it present in a case of rupture of the liver, in which the rupture was small, and down in the lobus Spigelii with the blood confined by liver, stomach and omentum so that the parietal peritoneum was not flooded In one case of severe bowel injury he failed to find it although the abdomen was full of blood

Claybrook is positive that abdominal rigidity has no bearing on the production of the sign, as he has found it in perfectly soft, flaccid abdomens, as well as in those that were rigid The fluid itself could not be responsible, for it is too little in amount in many cases, and besides fluids do not carry these sounds as well as gas, or the tissues He has found the sign present in cases of ruptured mesentery with hemorrhage, ruptured spleen, ruptured bowel, ruptured liver ruptured tubal pregnancy, and immediately after rupture of an appendix It is not present in postoperative cases The sign is not found in a slowly developing effusion, as in peritonitis or ascites

4. Infection of Children with Bovine Tubercle Bacillus.—Mitchell investigated seventy-two consecutive unselected cases of tuberculous cervical lymph-nodes in children; of these, thirty-eight resided in Edinburgh and thirty-four came from neighboring country districts (within a radius of 30 miles). Experimental animals were used in every case. Guinea-pigs were inoculated with tuberculous material as soon as possible after receiving it, and the lesions subsequently developing were the immediate source of the cultures. It was found that the spleen and softened caseous lumbar lymph-nodes were the structures that yielded the best growing cultures.

It soon became evident to Mitchell that he had to deal with two distinct groups of tubercle bacilli, one of which far exceeded the other in virulence for the rabbit. The groups he has designated engonic (luxuriant) and dysgonic (sparse). The dysgonic (sparse) group is a very large one and contains sixty-five viruses. All the cultures of this group grow very sparsely or not at all on glycerin egg and are assuredly of the bovine type. The engonic (luxuriant) group grows luxuriantly on glycerin egg in primary cultures and succeeding generations and includes all the cultures of the human type. It is a very small group and contains only seven out of the seventy-two viruses investigated. This division into engonic and dysgonic viruses has corresponded in all cases with the difference in virulence in rabbits.

By his study Mitchell is convinced that cow's milk containing bovine tubercle bacilli is clearly the cause of 90 per cent. of the cases of tuberculous cervical lymph-nodes in infants and children residing in Edinburgh and district, and is responsible for by far the larger proportion of tuberculous cervical lymph-nodes in children during the milk drinking period of life (0 to 5 years). Bovine tuberculosis can, therefore, no longer be considered a negligible factor in respect to the spread of tuberculosis among children, more especially since unsterilized cow's milk in this country is a vehicle by which tubercle bacilli must most frequently be introduced into the bodies of children. Until the proper legislative measures are obtained it is imperatively necessary for the public to sterilize cow's milk for the feeding of children.

Regarding the channels of infection, the faucial tonsils have in tuberculosis of the upper deep cervical lymph-nodes an importance not hitherto well enough recognized or understood —that is, they act not only as most frequent portals of entry for the tubercle bacillus, but in a large proportion of cases a well marked tuberculosis of the upper deep cervical lymph-nodes is secondary to a small tuberculous focus in the tonsil. Mitchell so investigated the hypertrophied faucial tonsils removed from ninety children, in whom the cervical lymph-nodes showed no clinical evidence of tuberculous disease; six (6.5 per cent.) of these hypertrophied tonsils gave histologic evidence of tuberculous disease, while nine (10 per cent.) yielded positive results when inoculated into guinea-pigs. The bovine bacillus was present in three cases, and the human in one case. The high percentage of faucial tonsils in which the bovine virus was present, Mitchell thinks, is further striking proof of the frequency of tuberculous cow's milk as a source of infection.

5. Torn Semilunar Cartilages.—Robinson's method of treatment is as follows: The patient is lying straight with the knee held acutely flexed, or he is in the Trendelenburg position. A tourniquet is applied. The skin is swabbed over with petrol containing ½ per cent. of iodin to remove grease, and then painted with tincture of iodin, after which the joint is wrapped round tightly with four layers of gauze wrung out of a solution containing spirit (70 per cent.) and mercury biniodid (1 in 1,000). A transverse incision is made to extend backward from the inner border of the patellar tendon for 3 inches. Sometimes it is necessary to have a good look round, to use a hook and to rotate the leg, before the lesion is discovered. The wound is closed in three layers, the two deeper always with iodized catgut. The interrupted sutures in the capsule are placed widely apart to allow of transudation of the synovia, which is poured out after the operation, to escape into the tissues outside of the joint and thus prevent the pain which arises from distention of the joint. No drain is inserted. Robinson uses either iodized catgut for the skin incision, or silkworm gut (sometimes intracutaneously), or Michel's clips. The skin is painted again with iodin, and gauze, wool and a bandage is applied. No splint is applied: no sepsis occurs and the results are said to be excellent He reports twenty-two cases of torn internal cartilage and two of the external.

7. Treatment of Fractures of Elbow-Joint and Knee-Joint. —Treatment by full flexion (Jones' method), Hughes claims, applies to all fractures in the neighborhood of the elbow-joint, except fractures of the olecranon process, and most cases of fracture of the head of the radius. In these two latter open operation is preferable—namely, wiring the olecranon and often excision of the head of the radius. Of injuries in the neighborhood of the knee-joint, only those involving separation of the lower epiphysis of the femur and fracture of the shaft in the neighborhood of the condyles not involving the joint are considered. The displacement here is reduced under an anesthetic, and the knee is put in a condition of full flexion and held so for ten days or a fortnight and then is brought down to full extension and put up on a Liston's long splint, with extension below the knee.

10. Tumors of Bladder.—Three cases are reported by Newman: 1. Hematuria of six months' duration, blood at first small in amount, bleedings lasted only for a short time. Afterward hematuria frequent and copious. Pedunculated papilloma fixed to anterior wall; removed through suprapubic incision. No return of hematuria. 2. Hematuria of five months' duration, at first small in quantity and only at end of micturition, which act was sometimes difficult to begin, but was never painful. This was relieved after a portion of tumor came away spontaneously. Simple pedunculated papilloma at base of bladder, removed through suprapubic wound, no return of hematuria. 3. Hematuria during six months, at first small in amount, only occasional, and unaccompanied by other symptoms; later continuous, and accompanied by other symptoms; later continuous, and accompanied by frequent micturition, finally by incontinence, and severe pai

30 *Infective Nature of Certain Cases of Splenomegaly and Banti's Disease A G Gibson
31 Pneumopericardium J Cowan, A W Harington and J R Riddell
32 Pituitary Body E Goetsch

27 **Intracranial Serous Effusions**—Warrington summarizes his views as follows The effusion may be the important pathologic fact, and the prognosis and treatment depend on a recognition of this The progress of an inflammatory effusion within the skull may be arrested at the serous stage The primary cause is commonly a near or distant focus of septic infection, the toxins formed by this, but not the micro organisms, stimulate the vessels of the meninges, brain or ependyma and choroid plexuses to the formation of excessive fluid The primary cause may also be toxins generated by non pyogenic organisms, and in rarer cases the excessive fluid results from causes other than toxins of microbic origin The symptoms in the acute or chronic conditions, respectively, may simulate the gravest form of brain disease The diagnosis is suggested when there is reasonable evidence that the symptoms are those of increased intracranial pressure, if other well known conditions can be excluded, and it is strengthened by the recognition of the primary cause

28 **Formation of Acute Gastric Ulcers**—Elliott found that the substance tetrahydro B naphthylamine hydrochlorid, when injected subcutaneously in guinea pigs, causes the formation of acute gastric ulcers These result from the action of the gastric juice on the damaged mucous membrane, and they do not appear if the stomach is kept empty of food The ulcers form in one or two hours, and they heal with great rapidity, unless they chance to become septic Repair epithelium covers the raw surface within three days, and from this the glands are regenerated later The drug was dissolved by heat to a 1 per cent solution in neutral Ringer's fluid or in normal saline On cooling, a yellow solution was obtained, which slowly darkened with keeping, while a brown precipitate appeared in the course of a few days A fresh solution was generally employed This was injected subcutaneously over the abdomen

No signs of pain at the site of injection were caused, but in ten minutes or so the general toxic effects appeared The hairs were raised over the shoulders and down the back, and the eyes were widely dilated, while the animal (cat and guinea pigs) became very restless and shook its head up and down Later, irregular convulsive movements appeared in the body and limbs, and the hind legs were partly paralyzed There was no evidence of asphyxia by constriction of the bronchioles If the dose of the drug was excessive, the phenomena of paralysis increased, so that the animal lay feebly on its side with the legs twitching weakly, and death followed in a few hours This fatal result might occur with 2 to 4 c c of 1 per cent solution

With an appropriate injection the phenomena of excitement and poisoning passed away in a few hours, and the guinea pig became to all outward seeming perfectly normal again It ate its food eagerly, and ran about the cage without any token of gastric discomfort None the less, acute ulcers were then always found to be present in the stomach, if the animal were suddenly killed The ulcers developed with great rapidity One or two hours after the injection, ulceration was always visible in the stomach Externally, this could be recognized by purple colored patches of congestion seen through the peritoneal coat Within, the damaged area looked much as the stomach does when a corrosive acid has been swallowed, an irregular swollen patch of hemorrhage and erosion being surrounded by a wide margin of a grayish color without hemorrhage These changes always occurred in the stomach Occasionally small hemorrhagic areas were also visible in the mucous membrane of the colon, cecum and duodenum These were caused by extravasation of blood from congested small venules, but the cells of the overlying mucous membrane seemed to be normal

No deeply situated foci of destruction were ever observed The appearances were simply those of a necrosis and erosion spreading downward from the surface, first through the protecting sheet of epithelial "mucous" cells, and then rapidly down the framework of the tubules The cells seemed to be loosened from their basement membrane by the action of the invading gastric juice before they were actually killed and digested In one hour after the injection the necrosis may have extended down through the entire depth of the mucous membrane Repeated injections were given in a few cases Each fresh injection was followed by the formation of some fresh ulcers, and the old ulcers remained septic, so that they extended through the muscularis mucosa, and even to the peritoneal coat Apart from the spreading effects of such sepsis, there was no tendency noticed for the ulcers to remain and pass into a chronic state Consequently, the experiments were not carried any further

29 **Bronzed Diabetes**—The most helpful outcome of the work here placed on record is the evidence which is afforded that, in cases of hemochromatosis, the accumulation of iron in the tissues is not, like the deposits of iron in cases of hemolytic anemia, due to any excessive destruction of blood corpuscles but rather to a failure to excrete iron by the usual channels The investigations confirm those of others who have failed to find evidence of undue hemolysis in cases of the same kind, and tend to support the view put forward by Parker that the iron set free in tissue catabolism fails to be got rid of, and so accumulates

30 **Infective Cases of Splenomegaly and Banti's Disease**—In the spleen of six cases, three with the picture of Banti's disease, two with splenic enlargement and fibrosis, and one with splenomegaly examined by Gibson, there was found, by a special method of staining, an appearance which he interprets as a parasitic invasion of the organ by a streptothrix organism, this being in such a relation to the affected parts at least in the cases of Banti's disease as to leave no doubt in his mind that they are the cause of the pathologic condition Many other spleens examined with the same object in view, several of which had pigmented spots, showed no such appearances Two different appearances are described, one being present in four cases the other in two, which at first sight suggests two different species of streptothrix The stain with which the possibility of a parasite becomes a certainty is Wheal and Chown's method for staining clubs in actinomyces; briefly, it is a double stain, first by hemotoxylin, then by carbol fuchsin, the decolorization being effected by equal parts of absolute alcohol and saturated watery picric acid No cultural proof is yet available that these structures are parasites

33 Teething and Growing Pains.—Gaujoux comments on the way in which mothers ascribe everything wrong in their children from the first to the sixteenth year to teething, worms or growing pains From these three scientific verities have grown great popular errors, leading to the neglect of symptoms of unsuspected cystitis, digestive disturbance or tonsillitis when a child has fever summarily ascribed to dentition, or bone or joint processes explained as "growing pains" Systematic examination of stools has shown that helminthiasis cannot be incriminated in fully 90 per cent of the cases but his own experience has shown that tapeworm is liable to be found in even young children who eat very rare beef, and that it is well to examine the stools for parasites in every case of anemia of obscure origin He emphasizes also that there is certainly a local inflammation when a tooth makes its appearance, and the child's resisting powers are correspondingly depressed, rendering it more susceptible to morbid factors The fact of growth, also, determines or favors various disturbances for which the physician should be on the lookout, retarded growth, stoppage or too rapid growth, pains from the latter, albuminuria at some stage of growth, menstrual anomalies, nervous troubles, headache, tendency to malformation in the chest or spine, palpitations, dyspepsia, etc The physician should be thoroughly posted on all these and detect them in their incipiency in children in his charge Inadequate respiration is an important factor, he thinks, in these growth disturbances, and in every case the task is to distinguish between the influence of the growth and of pathologic factors, as dentition and growth are essentially physiologic processes

37 Whooping-Cough—Dumas reviews the present status of our knowledge in regard to pertussis, stating that the evidence to date seems to incriminate the Bordet Gengou bacillus and open a vista for promising treatment The testimony yet in its favor is still far from conclusive He adds that in tedious cases with frequent paroxysms of coughing, morphin may render useful service unless contra indicated by albuminuria

45 *Iodin Treatment of Tuberculosis L Boudreau

45 Intensive Iodin Treatment of Pulmonary Tuberculosis—Boudreau regards iodin as the direct, specific and heroic procedure for tuberculosis, and declares that it transforms the system in a way amounting to a complete immunization, modifying the organic habits He has been giving it systematically for the last ten years in treatment of pulmonary tuberculosis, pushing it to the limit of tolerance The patient takes it in his beverages; it has a disagreeable taste only in plain water He has used various preparations of iodin but prefers the tincture (the French tincture of iodin contains 1 part iodin to 12 parts 90 per cent alcohol) He commences with small doses, carefully testing the tolerance, insisting that pure iodin is not so liable to cause symptoms of iodism as its salts From 20, 60 or 100 drops a day of the tincture of the iodin, the patients pushed the doses themselves to 200 or 300 drops a day, carefully fractioned, one patient took 400 drops for a time in the summer without the slightest inconvenience Signs of iodism were extremely rare and so slight as to be generally negligible His experience has been mainly with pulmonary tuberculosis, but his results with renal tuberculosis were also so encouraging that he urges a thorough trial of the iodin treatment before removing a kidney for a tuberculous process Iodin is the wonderful exception, he says, among microbicidal substances in that, fatal for microbes, it is a tonic for human beings The dosage has to be individualized, some of the apparently mildest forms of pulmonary tuberculosis proving most tenacious and vice versa Children of 6 or 7 take up to 40 or 60 drops a day without signs of intolerance

49 Direct Transfusion of Blood Suturing Artery to Vein Briau

46 Resection of the Throat for Cancer—Two cases are reported and other recent cases from the literature are briefly cited The immediate mortality was 19 per cent including seven cases of early recurrence The technic is discussed and the fact that the operation on the pharynx does not seem to enhance the danger of the intervention as the region is accessible With laryngectomy alone, drainage is so imperfect that gangrene cannot be warded off In the cases cited, three of the patients are in good health after intervals of seven years, four years and three years among those whose fate is known

48 Thyroid Grafting.—Paschoud gives three colored microphotographs besides a number of illustrations in the text accompanying his history of thyroid grafting and account of his own work in this line Thyroid tissue seems to be particularly favorable for engrafting, it frequently lives grows and functionates, and this method of treating myxedema and cachexia strumipriva is not to be disdained No benefit is known to date from thyroid grafts in tetany and cretinism At the same time, Paschoud remarks, he has been unable to find in all the literature even one case in which the remote results were favorable enough to justify the assumption of any real efficacy from the thyroid grafting operation He relates the case of a woman who had a tumor develop in the region years after removal of a parenchymatous goiter It was removed at the sixth year Again a tumor developed in the region, this time in the scar, and this tumor was removed eight years after the second Each of the tumors had all the characteristics of thyroid tissue and he is convinced that each developed from an engrafted scrap of the thyroid during the preceding operation The bibliography on thyroid grafting closes the article, a list of 147 titles

61 Jaundice after Abortion; Two Cases. Anderodias and Dronin

59. Gastro-Intestinal Hemorrhage from Breast Milk.—The new-born child of a supposedly healthy woman had hemorrhages from the stomach and bowels as it began to nurse its mother. The child was transferred to an incubator, and another newly born child placed at the woman's breast. In a day or so this infant also developed gastro-intestinal hemorrhage, and a third infant given her milk vomited a yellowish fluid. Analysis of the breast milk showed only 16 gm. fat but 36.9 gm. casein by weight per thousand; the normal average is respectively 40 and 11 gm.

Semaine Médicale, Paris

January 7, XXXIV, No. 1, pp. 1-12

62 *The Loose Uterus. (L'utérus ballant.) F. Lejars.

62. The Flopping Uterus.—Lejars applies this term to the freely movable uterus which alters its position, swaying to right or left, backward or forward at will, and thus giving rise to intermittent symptoms in puzzling variety. In one such case the fundus of the uterus could be felt in the posterior cul-de-sac, enlarged and tender. The evening before the operation to correct the exaggerated retroflexion, the displacement was determined anew, but when the abdomen was opened the fundus was found to have flopped over in the night and was in anteflexion. The ligaments were shortened, the appendix was removed, and all disturbances were cured. If the possibility is once thought of that the fundus of the uterus may be free to move around, this will often explain puzzling syndromes which suggest trouble in the adnexa, or tumors, etc. The disturbances are generally increased during menstruation. Repeated examination, with the pelvis raised or lowered, will generally reveal the excessive movability of the uterus; an abnormally long and flexible isthmus is the cause. Shortening the ligaments may cure all the disturbances and again it may not. Lejars says it is not a question of operative treatment but of general therapeutics, often quite complex, the various elements of which must be sought out and studied. He quotes Hölder's statement that in 142 cases of movable retroflexion, corrected by the Alexander-Adams operation, one-third of the women in whom the orthopedic result was nil had no disturbances, while a third of those with perfect orthopedic outcome yet suffered from functional disturbances. The functional outcome is due less to the attitude of the uterus than to the cure of complications, prolapse or endometritis.

69 Gall-Stone Found in Liver. S. Siber.
70 Case of Acute Erotic Paradidymitis. J. Heller.

66. Leukemia.—Hansemann is convinced that some acute infectious disease is the forerunner of leukemia and allied conditions. Acute leukemia is in itself the clinical picture of an acute infectious disease or intoxication. Many of its manifestations resemble those of severe diphtheria and other septic diseases; but the differences must also be emphasized, the noncontagiousness, and the impossibility to date of transmitting the disease to animals. One writer has recently stated that he had found a history of malaria in all his cases. There is much to sustain the hypothesis that the tonsils are generally the primary seat of the infectious process. Hansemann urges all to investigate the previous history in every case of leukemia so that a composite picture may be obtained as to the infections passed through before the onset of the leukemia. If these data in cases of leukemia are reported to him, he will compile and compare them and with a little cooperation in this way much light may be thrown on the leukemias. (His address is Prof. Dr. D. von Hansemann, Winklerstrasse 27, Grune, Berlin, Germany.)

67. Operative Treatment of Exophthalmic Goiter.—Klose expatiates on the increasing safety and benefit from operative treatment in Basedow's disease since the practice has been adopted of resecting the thymus along with the thyroid, or removing the entire thymus. The danger with thyroidectomy in exophthalmic goiter seems to be acute intoxication from the thymus after the thyroid is gone. At Rehn's clinic there were eight deaths from this cause alone—"thymus deaths"—in 130 operative cases of exophthalmic goiter up to 1911, but since then the thymus has been resected along with the thyroid, and there have been no deaths in the 200 cases. The capsule of the thymus is left, as its removal is liable to bring on serious hemorrhage. The operation is simple and easy but there must be a week or two of preparation, psychic, dietetic and medicinal. General anesthesia is not used; ice is applied to the goiter and heart. Local anesthesia and systematic accessory resection of the thymus have placed the surgical treatment of Basedow's disease on a new plane.

68. Radiotherapy of Uterine Cancer.—Heimann reports eighteen cases of inoperable uterine cancer in which remarkable benefit was realized in all but five from exposure to mesothorium and Roentgen rays. In six of the patients the improvement amounts to a clinical cure, and he witnessed no by-effects from the exposures in any instance. He gives the microscopic findings in a scrap from a cervix cancer before and after the exposures, showing the complete disappearance of the numerous cancer nests.

71. Heatstroke, Sunstroke and Electric Accidents.—Grober reiterates that in these conditions artificial respiration can never be applied too early nor kept up too long, but with heat or sunstroke it must be done cautiously not to bring on or exaggerate cerebral hemorrhage. Especially as the patient revives, attention should be paid to possible paralysis from this cause and the necessity for quiet which it imposes. Resuscitation has often occurred after ten or twelve hours of continuous artificial respiration. When the veins are much congested, generally in elderly, plethoric persons, and also in case of emphysema of the lungs or chronic bronchitis or tuberculosis, venesection, withdrawing 250 or 400 c.c. of blood may be useful; supplementary saline infusion is not needed. In presence of heatstroke, the physician must not forget in his solicitude for the patient to look after the welfare of others and ward off further cases of heatstroke, as the same meteorologic and other conditions are liable to affect a number of persons at the same time. A tendency to convulsions or delirium with either heat or sunstroke may require small doses of some sedative and it should not be withheld too long. In treatment of electric burns he has found most useful a liniment of lime water and olive oil in equal parts.

With an accident from a high power electric current, artificial respiration should be renewed again and again even after all hope seems lost; massage of the heart may also prove useful. Lumbar puncture has rendered good service in some cases. To get rid of the degeneration products caused by the passage of the powerful current through muscles and liver, venesection and saline infusion have proved useful in many cases after the emergency indications with regard to respiration and circulation have been met.

72. **Operations on Diabetics.**—Kraus gives the experiences and views of Payr, Naunyn, Minkowski and von Noorden in this line, and Karewski reviews his own experience with surgical treatment for thirty years all on the same principles. He states that seven of sixty-eight diabetic patients died of coma after operations on aseptic tissues, that is, 11.8 per cent. The mortality from coma in sixty-nine cases of operations in infected tissues was fifteen, that is, 21.7 per cent. He insists on the necessity of examining for diabetes every patient before every operation, as diabetics require treatment according to the strictest principles of internal medicine before, during and after any surgical measure. Under aseptic conditions, the wounds heal smoothly but infectious processes run a malignant course and increase the danger of the constitutional disease. He would restrict all operations on diabetics to those with vital indications or when necessary to restore the earning capacity. With these limitations, diabetes should not modify the usual principles of surgical procedure. Naunyn regards postoperative coma as an acidosis. All emphasized the greater susceptibility to infection, and the unfavorable influence from any operation on the course of the diabetes by the psychic shock, the injurious influence of the anesthetic, loss of blood, restricted diet and more or less impairment of the respiration and circulation. Minkowski says that suspicion of diabetes should compel the minutest asepsis and avoidance of all antiseptics liable to have a toxic action, refraining from constricting bandages, infiltration anesthesia, ligatures *en masse*, etc., with special care for the diet and supply of alkali to neutralize the acid.

74. **Thread-Test for Gastric Acidity.**—Schwarz uses a solid gelatin capsule containing a heavy powder giving a neutral reaction. The capsule is pierced and a thread drawn through it which has been soaked for half an hour in a 0.25 per cent. aqueous solution of congo red. The thread is 120 cm. long and after passing through the capsule, is tied over it and the capsule is then swallowed half an hour after a test breakfast. The free end of the thread is held in the hand. After fifteen minutes the thread is drawn out, the capsule having dissolved in the stomach in the meanwhile. The end of the thread which has been in the stomach is now dark blue or violet proportional to the amount of hydrochloric acid in the stomach content; if the thread is still red, this shows anacidity or that the capsule has stuck somewhere on its way. By this simple means the condition in regard to acidity in the stomach can be determined without inconveniencing the patient.

85 Aviation and the Eyes. (Die Augen der Luftfahrer.) Halben. Concluded in No. 2.

80. **Tuberculous Epididymitis.**—Anschütz discusses the questions whether the testicle is liable to become involved; whether removal of one testicle and epididymis will prevent the involvement of the other side; the influence on the outcome of tuberculous lesions elsewhere; the influence of castration on a tuberculous process in the prostate and seminal vesicles, and, lastly, what are the consequences of double castration. He tabulates the details and later history in 174 cases of unilateral castration; recurrence followed in three years or later in only 30 per cent. The condition of the prostate and vesicles at the time of the operation seemed to have no influence on the ultimate outcome. Double castration was followed by complete recovery in 82 per cent of the twenty-eight cases free from other tuberculous complications outside of the prostate and vesicles but only 17 per cent. were living three years later of the twenty-three with complications elsewhere. Tuberculous epididymitis not given operative treatment spreads to the other side in from 50 to 75 per cent. of all cases. When both sides are involved, he advises unilateral castration and conservative resection or curetting on the other side, unless there is already a fistula on both sides, when double castration should be the rule. Microscopic foci in the testicle are liable to heal after removal of the epididymis. Further experience in this line is urgently needed to determine whether this alone is sufficient in case one side only is affected. Anschütz has prepared some question-blanks to collect data on this subject, and will gladly send some on demand. (His address is Prof. Dr. W. Anschütz, Kiel, Germany.)

81. **Treatment of Non-Malignant Stenosis of the Pylorus.**—This article is practically a sequel to the one summarized in THE JOURNAL, Dec. 6, 1913, p. 2110. Boas here gives minute details how to determine the exact condition in the stomach, and means to combat insufficiency of the pylorus. Residue in the stomach twelve hours after a meal indicates that the pylorus is obstructed but not necessarily that there is dilatation of the stomach. With dilatation there is a pronounced succussion sound on slow change of position; a splashing sound is not decisive, at least fasting. With stenosis, part of the stomach wall stiffens or bulges on systematic rubbing of the fundus. The degree of stiffening or bulging is proportional to the extent of the obstruction offered by the pylorus. The presence of residue can be determined by roentgenoscopy but Boas prefers his test supper and examination of the stomach contents next morning as more instructive.

The degree of stenosis is readily determined by giving fasting 400 c.c. water to which have been added fifteen drops of an aqueous solution of some stain (chlorophyl) and after half an hour the stomach contents are forced out by expression or siphoned out. If not more than 50 c.c. of the water is found then in the stomach the pylorus must be regarded as normally permeable. A more convenient but less reliable means is by measuring the intake of fluids and total output of urine; this should be done for eight days to be approximately reliable. If the twenty-four-hour urine totals 500 c.c. or less the stenosis must be serious; with 500 to 800, moderately severe, and above this merely slight stenosis may be assumed.

In treatment the aim must be to modify the diet until there is no retention. Exclusively fluid but nourishing food at first, milk, cream, eggs, fruit, meat jellies and vegetables in pulverized form. If there is no residue with this, after three or four days one or two rolls or zwieback can be added, gradually adding soft mashed potato, and other vegetable *purées, beaten omelet, etc. If not enough of the above* to sustain the patient's strength can be taken without residue, the surgeon should be called in unless the patient learns to expel

120 *Influence of Emotions and Mental Strain on the Heart. (Einfluss der Gemuthsbewegungen und geistiger Ueberanstrengung auf das Herz, insbes. auf die Entstehung der Arteriosklerose.) J. Pawinski.

120. Influence of Emotions and Excessive Brain Work on the Cardiovascular System.—Pawinski says that the human brain manifests its feelings through the heart. The intimate connection between the emotional sphere and the action of the heart is a long familiar fact, but it can never be reiterated too often as the physician by suggestion rather than drugs can be such a power for good in many cases. Among 25,000 cases of cardiovascular disease, Pawinski found that grief or worry had been an important factor in 8.6 per cent. of 3,156 cases of arteriosclerosis in men; it seemed to be the exclusive factor in 3.2 per cent. The corresponding figures for angina pectoris were 13.4 per cent. in 1,074 cases. It ranks fourth here in the list of manifest factors, following tobacco, obesity and alcohol in turn. In women, obesity is the predominant factor in angina pectoris, but next to this emotional stress; the marked influence of grief or worry was evident in 14.2 per cent. of 224 cases of angina pectoris in women. It seemed to have been the exclusive factor in 1.1 per cent. and also in 4.1 per cent. of 943 cases of sclerosis of other vessels.

Excessive brain work could be incriminated in 9.2 per cent. in 1,075 cases of coronary sclerosis in men; alone, in 1.9 per cent. In 2,081 cases of sclerosis of other vessels, it could be incriminated in 4.5 per cent.; alone in 1.7 per cent. Excessive brain work thus is, next to syphilis, the leading factor in sclerosis in men. Grief, worry and excessive brain work, especially when combined, depress the innervation of vital organs and derange the metabolism, and the cardiovascular apparatus bears the brunt of the disturbance first and foremost. Of all occupations calling for mental effort under unfavorable conditions, the medical profession, he declares, takes the lead. Excessive mental, emotional and even physical stress, the demands on their sympathy, are the cause of the frequent development of arteriosclerosis in physicians. Lawyers have to work under similar but less wearing conditions, also big manufacturers, bankers, authors, and the leaders of political parties.

133. Salvarsan Ineffectual in Rabies.—Mejia tabulates the results of his experiments all showing that salvarsan even in doses proportionately much larger than is possible in the clinic had no appreciable effect on experimental rabies in eighteen rabbits. In these and in other series of animals and in rabies in human beings treated with salvarsan, inoculation of sound animals with a scrap from the medulla was invariably followed by the development of rabies.

134. Permeability of the Meninges Important Factor in Treatment of Tabes and Paresis.—Viton found that reactivation of the permeability of the pleura was an indispensable element in the cure of pleurisy, and his success in this line suggested that the non-permeability of the meninges was the cause of the ineffectual action of drugs in syphilitic affections of the central nervous system. By inducing a slight chemical irritation in the meninges they are rendered permeable, and he has taken advantage of this fact to good effect. Artificial serum can be injected into the spinal canal for the purpose or a mild disinfectant. Sicard recommends a mixture of 0.1 gm. of mercuric cyanid; 0.015 gm. of novocain and 2 c.c. of 5 per thousand salt solution. He injects part or all of this amount and repeats it a month later, pushing mercury or salvarsan in the interim. Viton has thus succeeded in materially relieving tabetic patients with gastric crises or lightning pains, the improvement being constant and marked. He has found mercury as effectual as salvarsan when given by this technic, while he regards it with greater confidence. The intraspinal injection is sometimes followed by pains or sensations of heat in the legs, but this is transient. When the fluid is suspected of being under high pressure he has the patient lie on his side, and he withdraws 8 or 10 c.c. of the fluid and gently injects 1 or 2 c.c. of the cyanid solution, not allowing the patient to sit up afterward for fifteen or twenty hours. Viton is professor of clinical medicine at the university of Buenos Aires.

THE PHENOMENA OF INFECTION *

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

Doerr[1] of Vienna closes an excellent review of recent work on so-called anaphylaxis or protein sensitization with the following paragraph:

> While it must be admitted that the action of those infective bacteria which are not known to produce specific toxins remains without explanation, and while the theories which have been developed by von Pirquet, Friedberger, Vaughan, Schittenhelm, Weichardt and others have opened up a new way to the understanding of incubation, fever and crises, still it must be borne in mind that the premises of these theories do not possess the force of demonstrated facts. It has not been positively shown that the symptoms of anaphylaxis are due to the parenteral cleavage of proteins, that the true anaphylactic poison is identical with that produced *in vitro* and that both come from the antigen. Even if we agree with Dold, Sachs and Ritz that so far as the rôle of anaphylaxis in the infectious diseases is concerned, it is irrelevant from what matrix and by what processes the hypothetic anaphylactic poison is produced, even then not all the difficulties are removed. Numerous infecting agents are not anaphylactogens; they do not differ in their effects on sensitized and non-sensitized animals, and even when there are differences they are slight compared with those seen when the protein antigens derived from the higher plants and animals are employed. The relatively simple structure of the bacterial proteins is the cause of this. Therefore it is questionable whether one has the right to explain the phenomena of the infectious diseases with serum sensitization as a starting-point. Moreover, the infections are not so monomorphic as some suppose from a superficial consideration. Measles and scarlet fever seem much alike; still, during an attack of the former the body cannot be sensitized to tuberculin or vaccine, while the latter does not induce this condition.

This statement, following as it does a fair but critical review of the new theories referred to and the work on which they rest, is certainly just. The purpose of this paper is to state the sensitization or parenteral digestion theory as I understand it and weigh the evidence for and against it. It should be plainly understood that in doing this I am speaking my own views, and it is probable that no one of the investigators with whom Doerr has done me the honor of grouping me would agree with me in all details, nor I with them.

It may be well to meet at the outset the chief objection which Doerr makes, in the foregoing quotation, to the sensitization theories. He states that the bacterial proteins have a relatively simple molecular structure. This is an assumption without a fact to support it. Because bacterial cells are relatively simple morphologically, it has been inferred that they are simple in the chemical structure of their protein constituents. This certainly is not true. My students and I have shown that the bacterial proteins are quite as complex as those of the cells of our own bodies. They contain at least two carbohydrate groups, one of which has been quite positively located in the nucleic acid fraction, while the seat of the other has not been determined. They furnish nuclein basis, thus showing the presence of one or more nucleic acids, which has been inferred from their behavior toward the basic strains. They yield diamino- and mono-amino-acids in like abundance and variety as these are found in the proteins of the higher plants and animals. In short, bacteria consist largely of glyconucleoproteins. Recent papers from Kossel's laboratory[2] confirm my assertion that the chemical structure of the bacterial proteins is not simple.

Doerr's statement that numerous infective agents are not anaphylactogens is one which I can neither confirm nor deny. It seems to me, however, to be an assertion which needs qualification. There are many kinds and degrees of sensitization depending on the sensitizer and the cell acted on. In some instances the sensitized state continues for many years; in others it lasts for only a few weeks or months, while in still others it is even more ephemeral.

SENSITIZATION OR PARENTERAL DIGESTION THEORY

In order to save space and time I will formulate my views concerning the phenomena of infection as follows:

All infecting agents are living proteins capable of growth and multiplication. They may contain carbohydrates, fats and waxes, possibly other and simpler chemical bodies, but their essential and characteristic constituents are proteins. This is true not only of all infecting agents but also of all life units. The infecting agents which we know are bacteria, protozoa, molds and yeasts. These possess physical characters which enable us to individualize them, but theoretically there is no reason why a living thing, and consequently a virus, may not be a liquid. Each and every living thing must feed, assimilate and excrete. Its molecules must be in a labile state, taking in and casting out atomic groups simultaneously. The bacterium can feed only on the pabulum within its reach, and of this it can utilize only that which it can fit into its molecular structure. Only this is pabulum to the cell. Organisms which cannot utilize the proteins of the animal's body cannot be pathogenic to that animal. All living things feed through the activity of their ferments. These are of two kinds, analytic and synthetic. The former split up the pabulum into proper building-stones, while the latter places these stones in proper position in the cell molecule. Usually we say that cell ferments are extracellular and intracellular. The former diffuse more or less into the medium and exert a cleavage action; the latter remain in the cell and do a constructive work. That these ferments are in reality different bodies is indicated not only by the parts they play in the life of the cell, but also by the fact that they are differently affected by heat and chemical agents. Ferments are specific in two senses: first, each kind of cell elaborates its own ferment, and secondly, the ferment is able to split up only certain proteins. Besides, for each ferment there is an optimum temperature at which its action is greatest. There are many bacteria which cannot grow at body temperature. These organisms cannot be pathogenic. This is true of most saprophytic bacteria found in water. Then, there is the relation between ferment and substrate which requires a nicety of adjustment which is not thoroughly understood. Finally, in a general way an accumulation of fermentative products retards the action of the ferment.

---

* A lecture given before the Harvey Society of New York, Jan. 17, 1914.

[1] Doerr: Handbuch der pathologischen Mikroorganismen, Bd. 2.

[2] Tamura: Ztschr. f. physiol. Chem., 1913, lxxxix, 85.

It must be remembered that the body-cells, like the bacterial cells, digest proteins. They also elaborate analytic and synthetic or extracellular and intracellular ferments. These ferments have been especially studied in the leukocyte. The extracellular ferments elaborated in leukocytes are germicidal because they digest bacterial proteins, and they are destroyed by a temperature of 56 C. (132.8 F.). The intracellular ferment of the leukocyte is also bactericidal and for a like reason, but it bears a much higher temperature. Every living cell in the animal body, like every bacterial cell, elaborates its specific ferments. This has been demonstrated positively by Abderhalden[3] and his students.

It must be evident from what has been said that the pathogenicity of a given virus is determined by its ability or inability to grow in the animal body. Its inability to do this may be due to the fact that it cannot digest and therefore cannot feed on the proteins of the body, or it may result from the fact that the ferments of the body-cell digest and destroy the bacterial proteins. Herein lies the explanation of all forms of bacterial immunity, either natural or acquired. Toxin immunity is quite a different thing and will not be treated in this paper.

In case of exposure, the chance of infection depends on several variables, such as the number and viability of the organisms introduced and the state of health or capability of resistance on the part of the animal. In man the effectiveness of the defensive ferments is influenced by heredity, age, food and possibly other conditions. The great fatality of measles and tuberculosis among those peoples who have inherited no resistance to these diseases is well known. That infants and adults are physiologically protected to a marked degree against diphtheria, while children are largely without protection, has been demonstrated by Shick[4] and others. We have long known that typhus, plague, beriberi, scurvy and pellagra are most in evidence when abundance and variety in food are lacking, and the work of Osborne and Mendel,[5] McCollum and Davis,[6] Wellman and Bass,[7] Funk[8] and others on the vitamins promises much.

When the infecting organism multiplies rapidly and soon leads to general sensitization of the body-cells, the disease developed is acute. On the other hand, when the invading organism finds the conditions for its growth less favorable, multiplies slowly, and only imperfectly and locally sensitizes the body-cells, the disease is chronic. When the virus is widely distributed throughout the body and sensitization is general, the disease is systemic. On the other hand, when the virus and sensitization are restricted, the disease is local. In cattle and sheep the anthrax bacillus grows rapidly, becomes abundant in the blood, sensitizes generally, and consequently develops an acute systemic disease. On the other hand, in the hog the growth of the anthrax bacillus is restricted to the lymphatic glands, sensitization is equally local, and the disease is both local and chronic.

That a given pathogenic bacterium may grow in one animal and not in a closely related species is illustrated by the susceptibility of the ordinary sheep and the immunity of the Algerian variety to anthrax. Koch found that the bacilli of mouse septicemia and the cocci that induce necrosis multiply simultaneously in the white mouse, but when field-mice are inoculated with mixed cultures the latter infects while the former fails to develop. Even natural immunity is only relative and may be overcome (1) by massive doses of the virus, which was demonstrated by Chaveau for Algerian sheep; (2) by lowering the temperature, as shown by Pasteur for chickens, and (3) by starvation, as exemplified by Canalis and Morpurgo for pigeons; all with anthrax.

One very important thing that we have learned in recent years is that the ferments produced by the body-cells may be and are modified under certain conditions. The cell may form a wholly new ferment or one whose activity is so modified that it may be so regarded. It is either a new ferment or the old one greatly modified and intensified in its action. We have utilized this function of the body-cells for more than a hundred years in vaccination against small-pox, but this use has been wholly empiric until recently, when it was scientifically explained by the researches of von Pirquet. Small-pox virus is pathogenic to the man who has not suffered an attack of the disease or has not been vaccinated, while to the man who has recovered from the disease and to the one who has been properly vaccinated it is not pathogenic. By the introduction of the vaccine organism, which is a non-virulent form of the virus, the body-cells are trained, as it were, to digest and destroy its proteins, and this leads to the immediate destruction of the virus on subsequent exposure to the disease. The same principle holds in typhoid vaccination with the dead bacillus, now so widely and successfully practiced.

My students and I have convinced ourselves, at least, of the following:

1. The infective bacteria, taking the colon, typhoid, tubercle and the pneumococcus as types, contain an intracellular poison.

2. This is not a toxin because it is not destroyed by heat; it is not specific; it produces no antibody when injected into animals in increasing non-fatal doses.

3. These bacteria elaborate no soluble toxin or poison. In old cultures there may be a trace of poison, but this results from the autolysis of the cells and is not a cellular secretion.

4. This poison can be obtained in soluble form only after cleavage of the cellular proteins, which may be accomplished by superheated steam, dilute acids or alkalies.

[6] McCollum and Davis: Jour. Biol. Chem., 1913, xiv, 40.
[7] Wellman and Bass: Jour. Trop Med., 1913.
[8] Funk: München. med. Wchnschr., 1913, p. 2614

5. This poison is a group in the protein molecule.

6. It exists in all true proteins, in pathogenic and non-pathogenic bacteria and in vegetable and animal proteins.

7. It is a split product of the protein molecule.

8. It may result from the cleavage action of proteolytic ferments.

9. In most vegetable and animal proteins the poisonous group is neutralized by combination with non-poisonous groups; consequently such proteins have no poisonous action until they undergo molecular disruption.

10. The poisonous group is common to all proteins; it is probably not chemically identical in different proteins, but is so nearly so that its gross toxicologic action is the same. We designate it as the central or primary group in the protein molecule.

11. This primary group is poisonous because of the avidity with which it combines with secondary groups in the proteins of the animal body.

12. The specificity of proteins lies in their secondary, non-poisonous groups. It is in these that one protein chemically and biologically differs from another.

13. Biologic relationship among proteins is determined by the chemical structure of their molecules. There are as many kinds of proteins as there are kinds of cells.

14. The specificity of the infective bacteria does not lie in the poisonous group of their proteins, for this has the same action in all, but in the non-poisonous groups.

15. The poison that kills in all the infectious diseases is the same.

16. The symptoms of the infections differ on account of the organ or tissue in which the virus accumulates and where it is split up and its poison liberated.

17. The ferment which causes the cleavage of the bacterial proteins in the different infectious diseases is specific. How strictly this is true can be determined only by more exhaustive and exact study.

When a fatal dose of a living virulent culture of the colon bacillus is injected into the peritoneal cavity of a guinea-pig the following effects result: For a period of time which usually varies from eight to twelve hours the animal remains apparently normal. Its temperature may fluctuate slightly but not beyond the normal limits. The coat is not roughened and the position and behavior of the animal in no way distinguish it from its untreated fellows. This is the period of incubation, and varies within certain time limits; but within these it is fairly constant. During this time the bacilli are multiplying enormously in the animal body. They are converting animal proteins into bacterial proteins. This is largely a synthetic or constructive process. The relatively simple, soluble proteins of the animal's body with but little change are woven into the more complex structure of the bacterial proteins. The soluble proteins of blood and lymph are built into the cellular proteins of the bacteria. There is no liberation of the protein poison and consequently no disturbance in the well-being of the host. It seems plain from this that the multiplication of bacteria in the animal body is not the direct and immediate cause of the symptoms of disease. When multiplication is most rapid and unobstructed there are no symptoms, and, in fact, disease is not in evidence. During the period of incubation of an infectious disease the invading organism supplies the ferment, the soluble proteins of the animal body constitute the substrate, the process is constructive, simple proteins are built into more complex ones, no protein poison is liberated and no recognizable symptoms mark the progress of the infection. Still, in the development of the phenomena of infection the period of incubation is critical, and the rate at which the infecting virus multiplies during this time is an important factor in determining the final outcome. The more virulent the virus, the more rapidly does it multiply, and this means a larger amount of animal protein converted into bacterial protein. Rosenthal[9] has shown by means of his bacteriometer that the more virulent a bacterium the more rapidly does it multiply.

Somewhat abruptly there is a change in the behavior of our inoculated guinea-pig. The hairs behind the ears begin to stand out and soon the entire coat becomes rough. It no longer eats, but retires to one corner of the cage and seems to be in distress. Slight pressure over the abdomen elicits evidence of pain, and the temperature begins to fall and continues to do so until death. In case of recovery a rise in temperature is the first evidence of improvement. The characteristic lesion is a marked hemorrhagic peritonitis.

This somewhat abrupt change in the condition of the animal marks the end of the period of incubation and the beginning of the active disease. The animal cells have become sensitized and are now pouring out a specific ferment which digests the bacterial proteins. In the active stage of the disease, the animal cells supply the ferment, the bacterial proteins constitute the substrate, complex cellular proteins are split into simpler bodies, the process is analytic and destructive, the protein poison is liberated, the symptoms of disease develop and life is placed in jeopardy.

It must not be understood that the processes that characterize the period of incubation and those that develop the active stage of the disease are separated by a well-marked time line and that the former wholly cease before the latter begin. This is not my understanding at all. Growth may be extending in one part of an organ, such as the lungs in pneumonia, while the destructive process predominates in another part. Only those cells with which the bacterial protein comes in contact are sensitized, and sensitization may be quite localized.

We take a second guinea-pig and inject into its peritoneal cavity a fatal quantity of the dead cellular substance of the colon bacillus. In this experiment we cut out one of the factors in the development of an infection, the growth of the bacillus in the animal body. This has been done *in vitro* and we inject into the peritoneal cavity enough of the cellular poison to kill. When this is done the animal remains quite well for about four hours, after which it shows symptoms identical with those manifested by its fellow which had been inoculated with the living culture. The lesions induced in both animals are the same. We conclude from this experiment that a period of about four hours is required to sensitize the cells of the guinea-pig sufficiently to enable them to begin the cleavage of the bacterial protein and carry this process to the production of enough poison to so disturb the health of the animal that the effects come within the range of clinical observation. There are involved in the process of the incubation of an infectious disease two important functions: One is the growth of the invading organism and the other is the sensitization of the body-cells. The more rapid the growth of the virus and the greater the amount of foreign protein accumulated at the time when sensitization becomes effective, the more disastrous are the results. Fortunately, particulate proteins, like bacteria and protozoa, are not so effective in the production of sensitization as are the simple, soluble proteins, such as those of blood-serum. Cell penetration is probably essential to the most perfect sensitization. Equally fortunate is it that the living cellular proteins are not so suddenly disrupted by the ferments produced by the body-cells as are the simple, soluble proteins.

---

[9] Rosenthal: Arch. f. Hyg., 1913, lxxvi, 81.

To a third guinea-pig we administer a fatal dose of the free protein poison split off from some protein molecule either by chemical agents or by a ferment acting *in vitro*. In this instance we cut out the whole period of incubation, and the animal dies as quickly as it would from a dose of hydrocyanic acid. The infective agent has been grown artificially, the cleavage has been effected *in vitro* and the ready-formed poison acts with the promptness that characterizes the action of other deadly chemical poisons. These experiments have been repeated in my laboratory many times with varied proteins, living and dead, particulate and in solution, of bacterial, vegetable and animal origin, and with their split products. If I have correctly interpreted them, they throw much light on the phenomena of infection; but before we question the correctness of the interpretation we must proceed with our experimentation.

The older literature shows that a few observers have long known that the parenteral introduction of diverse proteins is followed by the development of fever. There is an article by Gamaléia,[10] written twenty-five years ago, to which I wish to call attention. The title of the article is interesting, "The Destruction of Microbes in the Febrile Organism." Gamaléia showed that fever followed the parenteral introduction of dead as well as living bacteria, either pathogenic or non-pathogenic. He concluded from these experiments that fever is not a phenomenon of bacterial growth in the body. He found that the less virulent the infecting organism the higher and the more persistent is the fever. A rabbit inoculated with the anthrax bacillus has a fever for only a few hours, when the temperature falls and death results, while one inoculated with the second vaccine has a fever of three days. When a rabbit is inoculated with a highly virulent anthrax bacillus, it may show little or no elevation of temperature, and dies within from five to seven hours. Gamaléia made similar experimental observations on other diseases and came to the following conclusion: The febrile process is not a result of the action of the bacteria, but, on the contrary, is due to a reaction of the organism against their presence and results in their destruction. I feel that I am fully justified in offering these experiments, made a quarter of a century ago, as supporting my theory or explanation of the phenomena of infection.

In 1909 it was shown by work in my laboratory[11] that fever could be induced experimentally in animals by the parenteral administration of proteins of diverse origin and structure, and that by modifying the size and frequency of the dose the type of the fever could be determined at will. We produced an acute fever, the temperature rising to 107 and terminating fatally in a few hours, remittent and intermittent and continued fevers. The last-mentioned furnished charts in no way distinguishable from those of typhoid fever. Not only can fever be induced, but its accompaniments also. In continued fever, thus produced, there is increased nitrogen elimination, emaciation, loss of appetite and lassitude and decreased urinary secretion. These experiments were amplified[12] and have been confirmed by Friedberger and others. Protein fever, which includes practically all clinical fevers, is a result of parenteral protein digestion. In this process the animal cells supply the ferment and the foreign protein serves as substrate. The foreign protein may be living or dead, formed or without form. It may be detached or dead tissue from the animal's own body, as after burns. It may be absorbed from some mucous surface, as in hay-fever. It may be introduced artificially, as in serum disease. It is usually a living protein, as in the infectious diseases.

There are two kinds of parenteral proteolytic ferments, non-specific and specific. The former are normally present in the blood and tissues, especially in the first. They differ in kind in different species and in amount and efficiency in different individuals. Their function is to digest and dispose of foreign proteins that find their way into the blood and tissues. Within limits they are general proteolytic ferments, as are those of the alimentary canal; but the variety of proteins on which they act is more limited. They constitute the most important factor in racial and individual immunity. We are immune to most bacteria and protozoa, not because they do not elaborate poisons, for every protein molecule contains its poisonous group, but because they are destroyed by the general proteolytic enzymes as soon as they enter the body and are not allowed to multiply. These non-specific parenteral ferments are probably secretions of certain specialized cells, as the leukocytes. Under normal conditions these enzymes are capable of digesting those proteins on which they act only in small amounts; but the cells which elaborate them may be stimulated in their activity. Whether or not these enzymes become specific when brought into contact with certain proteins has not been determined. The immunity secured by these enzymes is limited in extent and transitory in duration.

The specific, parenteral proteolytic enzymes are not normal products of the body-cells, but are brought into existence under the stimulation of those proteins, introduced into the blood and tissues, which on account of their nature or amount, escape the action of the non-specific ferments. A protein introduced into the blood and not promptly and fully digested by the non-specific enzymes is discharged from the blood-current and deposited in some tissue, the cells of which after a time develop a specific ferment which splits up this protein while it is not capable of digesting any other. For certain proteins there are certain predilection organs and tissues in which they are stored, either exclusively or most abundantly: the pneumococcus in the lungs, the typhoid bacillus in the spleen, mesenteric and other glands, the viruses of the exanthematous diseases in the skin, etc.

For the development of the specific proteolytic ferments time is required, and this varies with the sensitizing protein and probably with the tissue in which it is deposited. The development of these ferments necessitates changes in the chemical constitution of the protein molecules of the body-cells, and in this way the body-cells acquire a new function, which subsequently is brought into operation only by that protein to which its existence is due. As a result of this rearrangement in molecular structure the cell stores up a specific zymogen which is activated by contact with its specific protein.

[12] Vaughan, Cumming and Wright: Ztschr. f. Immunitätsforsch., 1911, ix, 458.

Whether or not the products of digestion with the non-specific ferments and those elaborated by the specific enzymes are identical remains to be ascertained. The presence of a poisonous group in the protein molecules is disclosed in both enteral and parenteral digestion as well as by cleavage with chemical agents or enzymes *in vitro.* In enteral digestion the poison is most apparent in the peptone molecule, which is large, complex and non-diffusible. Further action of the alimentary enzymes splits the peptone into harmless amino-acids. The cleavage of proteins by chemical agents is a crude process in which much of the poison is destroyed. When the poison is formed in the alimentary canal the animal is protected from its injurious effects by the walls and by its ultimate destruction. When the poison is liberated parenterally there are no protecting walls.

There are certainly other causes of fever, but the fever of the infectious diseases results from the parenteral digestion of the infecting agent by specific secretions elaborated by the body-cells; it is a phenomenon of the disposal of foreign and harmful material and it must be regarded as beneficent. There is a point, however, above which it becomes a danger *per se.* In parenteral digestion the following sources of heat production must be evident: 1. unaccustomed stimulation and consequent increased activity of the cells which supply the enzyme must be the source of no inconsiderable increase in heat production. 2. The cleavage of the foreign protein increases the liberation of heat. 3. The reaction between the product of the digestion and the tissues must lead to increased heat production. I regard the first and last of these as the more important sources of the overproduction of heat in the infectious disease. When the poison is liberated rapidly and abundantly the temperature falls and death is imminent.

There are many conditions which affect the course of a fever, and some of these may be mentioned. Some viruses sensitize more quickly and thoroughly than others. It is probable that the living cells, so long as they are living, do not sensitize. Some of the virus protein must go into solution before cell penetration, which seems essential to thorough sensitization, can occur. A living colon bacillus of not more than twenty-four hours' growth, when injected intraperitoneally into a guinea-pig, requires about ten hours to sensitize. With the dead bacillus the time is reduced to half, while with old autolyzed cultures in which the sensitizing group is already in solution the time is still further shortened. Some pathogenic organisms, like the tubercle bacillus, have been so long parasitic that they have learned to protect themselves by deposits of fats and waxes. In this way they are probably protected to some extent against the destructive ferments elaborated by the body-cells. In all acute infections the destruction of the invading organism is modified and delayed by the altered relation between substrate and ferment and the accumulation of fermentative products. All these questions are but little understood and their solution must await further research.

I have given the new theory of the phenomena of infection as I understand it. The attack on these problems has only commenced and I do not hold that my opinions possess in every particular the force of demonstrated facts. If they prove to be provocative of further and more exact research I shall feel that they have been justified.

EVIDENCE FOR AND AGAINST THE THEORY

I shall now take up some of the facts for and against this theory and try to make impartial statements concerning them. In the first place it is true, as Doerr states, that it has not been conclusively demonstrated that the poison formed *in vitro* is identical with that elaborated *in vivo.* In fact, we do not know the exact nature of the poison produced by the disruption of the protein molecule by chemical agents. I hold that this poison is a group in the protein molecule. Others question this and hold to the endotoxin theory as first elaborated by R. Pfeiffer. So long as the poison was obtained only from complex proteins such as bacterial cellular substances, the mixed proteins of blood-serum and egg-white, which is known to be a protein mixture, my opponents had an argument which I could not meet, but some proteins, such as edestin, are believed by all students of protein chemistry to be chemical units, just as much so as crystallized bodies. We take edestin and split it into poisonous and non-poisonous portions. We inject the former into a fresh guinea-pig and it kills the animal promptly after the development of certain definite and well-marked symptoms. We take another fresh guinea-pig and sensitize it to edestin and after a proper interval we give the same animal a second injection of edestin. This animal develops the same symptoms in the same time and in the same sequence as the other, and the post-mortem findings in the two are identical. We know that the edestin injected into the animal contains the protein poison which we may liberate *in vitro.* It seems that the only conclusion justifiable from these facts is that in both instances the animal dies from the same poison and that by the process of sensitization the capability of splitting up the edestin molecules has been developed. Besides, the blood-serum of an animal sensitized to egg-white will, when incubated with egg-white in proper proportion *in vitro,* produce a poison which kills a fresh animal with the same symptoms and with the same post-mortem condition as are developed on reinjection into a sensitized animal, while the blood of a fresh animal has no such action on egg-white *in vitro.* From these facts I draw the following conclusions: 1. The protein poison is a group in the protein molecule. 2. In a sensitized animal's blood-serum there is some agent capable of splitting up a protein and thus liberating a poison, and that something does not exist in the blood-serum of the unsensitized animal. If there be a fallacy in this reasoning I cannot see it. If it should be found that edestin and other proteins, believed to be chemical units, are not such, then my first conclusion is not wholly justified.

I do not assert that the protein poison formed *in vitro* by the chemical disruption of the protein molecule is identical with that elaborated *in vivo* by specific ferments, but that they are closely related chemically is inferred from their physiologic action. As I have stated, we do not know the chemical structure of the protein poison. We are certain that it is not an amino-acid, although it may be closely related to one of these. In its action the protein poison seems quite similar if not identical with the histamin of Barger and Dale. It will probably be found that the protein molecule contains a whole spectrum of poisons, one differing from another in some slight alteration in structure.

Years ago R. Pfeiffer demonstrated that cholera, typhoid, colon, and many other bacilli secrete no toxin, but that the cellular proteins of these organisms are poisonous. In the abdominal cavities of animals previously treated with these bacteria, when new injections are made, the bacterial cells dissolve like sugar or salt in water, but notwithstanding this destruction of the bacteria the animal dies. Indeed, death is due to the destruction of the bacterial cells and the consequent liberation of the protein poison. When the amount of cellular substance is insufficient to furnish a fatal dose of the poison, the animal survives and escapes infection. I regard Pfeiffer's phenomenon as the basis of lytic immunity, and it must be evident that this form of immunity is not in any way comparable to that induced by toxins. Pfeiffer was certainly wrong in explaining this phenomenon on the supposition that the bacterial cell contains an endotoxin. The harmful content of the cellular substance is not a toxin in the sense that this term is now used, but a poison.

The next important work done along this line was that of Weichardt, who found that the blood-serum of rabbits previously treated repeatedly with placental proteins dissolves the same both *in vitro* and *in vivo* with the liberation of a poison. This experiment was a forerunner of Abderhalden's test for pregnancy.

Schlecht[13] found that on reinjection of a sensitized animal the esosinophils are increased, and Chancellor[14] finds that there is also an increase in the same corpuscles on the injection of the protein poison. So far as it goes, this indicates that the poison liberated in anaphylactic shock and that formed from proteins by my method are similar in their effects.

The blood of an animal killed by anaphylactic shock coagulates slowly, while that of animals killed with the protein poison prepared by chemical agents coagulates in the usual time. This might be regarded as evidence that the poison formed *in vivo* and that prepared *in vitro* are not identical; but the agent which leads to retardation of coagulation may be one of the nonpoisonous groups liberated on the cleavage of the protein molecules in the body. The protein poison obtained by chemical means from certain proteins, such as the tubercle bacillus, however, does prevent the coagulation of the blood. This is the first evidence that I have found of any dissimilarity in the action of the protein poison as obtained from different proteins. It has been shown by Loewitt[15] and Waele[16] that a non-coagulable blood is not always in evidence in anaphylactic shock.

The fundamental fact in the work recently done by Abderhalden, the full import of which we cannot yet determine, rests on the development of ferments as a result of the parenteral introduction of foreign proteins. How strictly specific these ferments are is a matter which must be measured by larger experience.

Weinland first showed that invertase is developed in dogs by the parenteral introduction of cane-sugar, and this work has been amplified by Abderhalden, Heilner and others, until it has been demonstrated that the cells of the animal body can be trained to elaborate specific proteolytic, amylolytic and lipolytic ferments. The presence of specific ferments in the blood-serum is now being used in the diagnosis of pregnancy, cancer and dementia praecox.

If I correctly interpret the recently reported experiments of Thiele and Embleton,[17] they furnish strong evidence in favor of the theory which I have formulated. These investigators have developed the following points:

1. When the normal protective ferments of the animal body are inhibited in their activity, bacteria, which, under normal conditions are non-pathogenic, become pathogenic. It is well known that ferment activity may be retarded by hypertonic saline solutions. When such non-pathogenic micro-organisms as *Sarcina lutea* and *Bacillus prodigiosus* and others are suspended in from 2 to 5 per cent. salt solution and injected into the abdominal cavity of the guinea-pig, the normal lytic ferment of the animal is inhibited; the micro-organism multiplies and kills. In other words, a harmless bacterium is converted into a fatal one by holding in abeyance the normal protective function of the body. Years ago Buchner demonstrated that the alexin of blood-serum is highly sensitive to salt content and by variations in this the activity of the ferment may be hastened, lowered or wholly arrested. In this connection it may be interesting to record the fact that some physicians believe that a heavily salted diet predisposes to pneumonia.
2. The blood and exudates of animals dying of infectious diseases are shown by the application of the ninhydrin and biuret tests to their diffusates to contain protein-cleavage bodies which are not present under normal conditions. These proteoclastic bodies could hardly have their origin elsewhere than in the cleavage of the bacterial proteins.
3. These cleavage bodies found in the blood of animals dying of the infectious diseases develop typical anaphylactic shock in fresh animals when injected intravenously.

Edmunds[18] has shown that the physiologic action of my protein poison in dogs and cats is essentially the same as that manifested in sensitized animals on reinjection, and the same has been shown by several observers to be true in guinea-pigs. While identity in physiologic action does not establish chemical identity, it certainly suggests similarity in chemical structure.

Acute anaphylactic shock is so striking in its manifestations that it has delayed studies of chronic protein intoxications, in which, I doubt not, there lies a rich and profitable field of research. Every foreign protein finding its way into the blood and tissues is more or less injurious to the body-cells. It may be directly harmful or it may act through its split products. When it is repeatedly introduced, the body-cells become sensitized and split it up. When the intervals between the introductions are short there can be nothing like anaphylactic shock, but parenteral digestion has been established and the protein poison is liberated, possibly not in quantity sufficient to develop recognizable symptoms, but there results a chronic poisoning. If the theory which I have developed be true, the lesions of the infectious diseases are, in part at least, due to protein poisoning. Moreover, the disease needs not be an infectious one in order to lead to either acute or chronic protein poisoning. The absorption of undigested, or partially digested proteins from the alimentary canal may be quite as harm-

ful as inoculation with a living virus. It seems to me that we are now quite justified in speaking of the "albuminal diseases," including under this title all health disturbances due to the parenteral introduction of foreign proteins, be they living or dead, organized or unorganized. The description given by Richet of his experiments on anaphylaxis in dogs suggests strikingly cholera nostras in man. Schittenhelm and Weichardt induced an "enteritis anaphylactica"; in like manner, Friedberger[19] developed pneumonia in sensitized guinea-pigs by spraying horse-serum into the trachea. This has been confirmed by Ishioka,[20] and a careful histologic study of the lungs in this condition has been made by Schlecht and Schwenker.[21] It seems highly probable that we have been wrong in believing that all disease conditions are due to infections, many of which are secondary. In this connection I wish to call attention to the valuable research reported by Longcope,[22] who has induced nephritis in rabbits and dogs by repeated injections of horse-serum and egg-white. When we consider the care with which nature protects the body-cells from foreign proteins by the radical changes wrought in their structure by alimentary digestion, and since we know that every unbroken protein contains a highly poisonous group, we should proceed cautiously in the employment of serum and vaccine therapy. The value of diphtheria and some other antitoxins has been demonstrated, and the good accomplished with these agents constitutes one of the great triumphs of modern medicine; but much of the protein therapy now so largely employed is without scientific justification. I have tried earnestly to so disrupt the protein molecules of certain pathogenic bacteria as to obtain a non-poisonous, sensitizing group which might be of value in either prophylactic or curative treatment, but without practical success. I have obtained from the cellular substances of the colon, typhoid and tubercle bacilli non-poisonous sensitizing proteins. Those from the colon and typhoid give some degree of immunity to subsequent inoculation with respective living cultures, but the protection thus secured is low in degree and ephemeral, while that from the tubercle bacillus fails to protect experimental animals. I must therefore report failure with glimpses of that will-o'-the-wisp which haunts the laboratory of every investigator. In view of the great number of cleavage lines that run through the large protein molecule, it is not surprising that the gem with perfect facets, which one seeks, is not revealed at the first stroke of the hammer.

The studies of Pick and Obermeyer[23] confirmed and amplified by Landsteiner and Prasek,[24] render it highly probable that the specificity of the protein molecule is closely connected with its aromatic group. Furthermore, it is worthy of note that gelatin, in which the aromatic group is wanting, is not a sensitizer. The above-mentioned investigators have shown that when certain substitutions are made in the aromatic group of a protein it loses its specificity. It is also noteworthy that gelatin does not yield the protein poison when disrupted by our chemical method. It seems, therefore, that gelatin contains neither the sensitizing nor the poisonous group.

I must protest against classifying the toxins and anaphylactogens together under the name of "antigen." This term should be reserved for the former. The anaphylactogens produce no antibody. Pick[25] very properly states that diphtheria toxin does not elaborate a precipitin, agglutinin or hemolysin, and that it is not an anaphylactogen. He proposes that the toxins be designated as monovalent antigens in contradistinction to the polyvalent antigens, which elaborate numerous immune bodies. I can see no reason for calling the anaphylactogens antigens. The anaphylactogens are colloids of highly complex molecular structure, while the latest research points to the non-protein character of the toxin. As Pick states: Faust finds the active principle of cobra and crotalus venom to be a nitrogen-free sapotoxin; Abel and Ford report that the hemotoxin of *Amanita phalloides* is a glucosid containing nitrogen and sulphur; Bang and Forssmann state that the hemolytic component of the red corpuscle is a lipoid; Jacoby states that he has obtained a nitrogen-free ricin, and according to Burckhardt the hemolysin of *Bacterium putidum* is non-protein. Likewise, tuberculin is an anaphylactogen, or not according to the preparation. When free from other constituents of tuberculoprotein it is neither anaphylactogen nor toxin, but a poison. Tuberculoprotein contains an anaphylactogen group, but this does not constitute the active principle of tuberculin, which is of relatively simple structure.

Many investigators have failed to sensitize animals with tuberculin, while most have succeeded with dead bacilli and with aqueous extracts. This is not surprising; indeed, it is what should have been expected. Tuberculin consists of digested, denatured proteins of relatively simple composition. It is well known that peptones and polypeptids do not sensitize. The protein poison, when detached from other groups in the protein molecule, sensitizes neither to itself nor to the unbroken protein. The fact that tuberculin does not sensitize, or does so imperfectly, raises a serious question as to its employment as a therapeutic agent. It is undoubtedly an excellent diagnostic agent because its relatively simple structure favors its prompt cleavage when injected into an animal already sensitized by the disease. But if it is not a sensitizer its therapeutic good effect, if it has any such effect, must be confined to the possible establishment of a tolerance to the tuberculopoison. Sensitization to tuberculoprotein can be induced by bacillary emulsions, with watery extracts, and with the non-poisonous residue. If the sensitization secured by the last-mentioned agents is as good as that produced by the others, it has the advantage of not containing any poison. On the other hand, if the therapeutic effect desired consists in the development of a tolerance to the poison, tuberculin must be preferred unless we should use the more completely isolated poison.

Reducing Weight.—The famous George Cheyne, who was a man of enormous bulk, reduced himself by dieting from 32 stones (448 pounds) to proper dimensions. One of his aphorisms says: "Every wise man after Fifty ought to begin and lessen at least the quantity of his Ailment, and if he would continue free from great and dangerous Distempers and preserve his Senses and Faculties clear to the last, he ought every seven years to go on abating gradually and sensibly, and at last descend out of life as he ascended into it, even into a child's Diet." Put in other words, it reads—We eat too much after 40 years of age.—Sir William Osler.

GASTRIC TETANY

WILLIAM L. RODMAN, M.D., LL.D.
PHILADELPHIA

I wish to make record of what to me was a very interesting case, and the only one of gastric tetany encountered in my practice. Notwithstanding the fact that Kussmaul called attention to gastric tetany in 1869, comparatively little advance was made in its treatment until a surgeon, Mayo Robson, took up its consideration in 1898. Various theories were given as to its causation. First, Kussmaul, who described the disease originally, declared it to be due to a desiccation of the tissues, very much as is seen in cholera or cholera morbus, from non-absorption of fluids. Then again, it was thought by Albu to be due to auto-intoxication following dilatation of the stomach, with or without pyloric stenosis. Germain Sée and others believed it to be due to reflex irritation or irritability of the nerves of the stomach, and, lastly, it was thought that the presence of foreign bodies in the stomach might initiate gastric tetany.

The case I wish to report was that of a young man, aged 31, a chemist in the Dupont Powder Works at Woodbury, N. J., sent to me by his physician, Dr. J. M. Marcy of Merchantville, N. J. He came to me in July, 1912, with as typical a history of duodenal ulcer as I have ever encountered. He, like nearly all such patients, habitually went with sodium bicarbonate in his pocket, of which he partook freely and frequently in order to obtain relief. Like many others he had become accustomed to washing out his stomach from time to time, especially at night, when gaseous distention, eructations and spasms of the stomach were usually more distressing than during the day. He had never vomited, however.

The diagnosis of a duodenal ulcer having been made by both his physician and myself, he was sent to the hospital and prepared for operation. The stomach was found to be markedly dilated, I should say almost twice the usual size, and a large ulcer was found, more than an inch in diameter, on the distal side of the pyloric vein. In addition to this large ulcer there were numerous rather fine adhesions to the gall-bladder and transverse colon. I mention this because it may be that they had some influence (I question it, however,) in increasing the obstruction at the pylorus and producing a consecutive dilatation of the stomach. A no-loop posterior gastrojejunostomy was done, and for ten days his convalescence was absolutely uneventful. I never saw a patient do better in my life. So well was he on the tenth day that I told him he could leave his bed and soon thereafter go home. After being up all day walking about the hospital and feeling very well, he had a restless night and suffered a recurrence of the spasms of the stomach, of which he had complained before the operation, and which, he said, had frequently awakened him during the night. On the eleventh day following the operation, in the morning, about 9:30, he had a convulsion, which began in the fingers, soon extended to the forearms and also to the feet and legs; but there was no involvement of the arms, the thighs, or the muscles of the body, so the nurse who was present testifies. The resident physician saw him just as he was coming out of the convulsion. Both he and the nurse said that the patient's mind was absolutely clear throughout the attack, but he complained of "terrible weakness," and there was a marked acceleration of the heart-action with embarrassment of respiration.

The following day about the same time he had a very severe convulsion, which the house-surgeon fortunately witnessed from the beginning. The fingers were flexed at the metacarpophalangeal joints and extended at the tips, with the thumbs adducted, making a typical accoucheur's hand. The spasms of the forearms soon extended to the arms and of the legs to the thighs. The muscles of the abdomen also became involved, and the resident said that wherever he touched the man the muscles seemed to become as hard as steel. The mind was clear throughout the attack, but the patient complained greatly of weakness afterward. The pulse was 130; respiration was greatly embarrassed, although he was not cyanotic. A characteristic feature of this convulsion, and a subsequent one which I happened to witness, was that the face was drawn to the left side, the eyebrow was elevated, and the eyeball rolled up under the lid, so that only the conjunctiva could be seen. He had five convulsions in four days; then they ceased. I think their disappearance was largely due to the frequent and copious lavage of the stomach.

The interesting point in connection with this case is that the gastric tetany came on eleven days after a successful drainage operation, and so far as I know, it is the only one on record. Nearly all of the cases reported as having received surgical treatment were relieved promptly by a drainage operation, either a gastro-enterostomy, a pyloroplasty or a pylorectomy. Only a few have been treated by the latter method.

My patient made a satisfactory recovery, leaving the hospital in thirty-one days after the operation, or twenty days after the convulsions began, and is perfectly well to-day.

It is interesting to note that in practically every one of these cases that has been closely observed, either at operation or at necropsy, there has been a dilatation of the stomach, and this has been consecutive either to a benign or a malignant obstruction at the pylorus. In the vast majority of instances the obstruction has been benign, either a fresh ulcer or a cicatrix on the base of an old ulcer, but always there has been marked dilatation of the stomach. In a few instances pressure on the pylorus, the duodenum or both, seems to have been caused by a distended gall-bladder, by a large gall-stone, pancreatic cyst, or by some tumor making pressure in the vicinity of the pylorus and causing a consecutive dilatation of the stomach.

As marked evidence of this I will cite the report of a necropsy which was taken from a case-report in the *Proceedings* of the Pathological Society of New York.

"The patient, aged 44, was taken ill two days before his death. While occupied in a stable he was taken with a sharp pain in the abdomen, and when help arrived he was stretched on the floor, rigid. His head could be moved, but not his legs. He was said to be semiconscious. After three-quarters of an hour the stiffness of the legs and arms disappeared. The patient refused to be taken to a hospital, and remained in the stable until 4 or 5 o'clock in the afternoon, when he was taken with another sharp pain in the stomach, and passed into a condition of general rigidity, the arms drawn up over his head, and the legs spastic. About 8 o'clock in the evening he was taken with a similar seizure. He was then removed to St. Vincent's Hospital. Dr. Stumer made a diagnosis of gastric tetany. The patient was pulseless; respiration was slow, with respiratory oppression. After entering the hospital there appeared a general spasticity of the abdomen and extremities, at times accompanied by severe pain. After four hours the spasm relaxed, and during this time the pulse became almost normal. The temperature was subnormal. The abdominal distress persisted during the relaxation. He became able to speak, but not intelligently, nor enough to give an absolutely correct statement of his trouble and the previous status of his illness. After six hours he was again seized with an attack, accompanied by great respiratory oppression.

"After one and a quarter hours he died, apparently from asphyxia, with no relaxation of the muscles. An autopsy was performed. The stomach contained 4.5 liters of fluid. The musculature of the stomach was very much thickened, especially along the anterior border. There was no evidence of any change in the mucous membrane. The thickening appeared to be due not entirely to an edema, but rather to a muscular hypertrophy, and an increase in connective tissue, particularly in the submucosa. At the pyloric end of the stomach was an old ulcer which had led to marked constriction of the pyloric opening. The esophagus was longer than normal. *The position of the stomach in the body* was not normal. There were adhesions to the transverse colon, a long band extending from the omentum to the tip of the bladder, pulling the stomach over from its normal position." The parathyroid glands were not examined, according to the statement of the pathologist.

None of the theories as to the etiology of this disease are entirely satisfactory, but Mayo Robson, that very astute clinical observer, believes that gastric tetany is due to an absorption of the stagnant contents of a *dilated stomach which poisons the nerve centers* and thereby increases reflex irritation.

The only case on record of marked gastric tetany due to a foreign body is reported by Warbasse. It occurred in a human ostrich, a man who swallowed knives, screws, pins, tacks, nails, watch-chains, anything he could lay his hands on. The weight of the metallic substances pulled the stomach down, so as to cause a *kinking* at the pylorus, resulting in obstruction. This patient was operated on successfully by Warbasse, and it seems that the obstruction was the cause of the tetany, and that it, in turn, was produced by the sagging of the stomach, due to the heavy substances which the patient had swallowed.

The one point I wish to make is *that* the medical treatment of such cases is practically a failure. Nearly all of the patients die, at least 88 per cent., according to Brown and Engelbach,[1] who have most exhaustively investigated the subject and given the latest and most complete statistics. Furthermore, surgical treatment is usually successful. This treatment consists of a drainage operation to relieve the overdistended and irritable stomach. It should be accomplished by a gastro-enterostomy, pyloroplasty or pylorectomy, according to the nature of the lesion causing obstruction. In simple, cicatricial stenosis of the pylorus, gastro-enterostomy satisfactorily meets the indications, whereas in fresh ulceration or malignant disease causing obstruction, pylorectomy should be preferred. When due to foreign bodies, gastrotomy and their removal of course, should be practiced.

Frequent and thorough lavage of the stomach does a great deal of good in lessening the number and severity of the gastric spasms and general convulsions, but evidently does not prevent them, as my case conclusively shows. The patient was accustomed to washing out his stomach before operation, and it was thoroughly practiced twenty-nine times after the convulsions *began and before the patient* left the hospital. It was amazing how much his stomach would contain when lavage was practiced; always pints and occasionally quarts of a thin, greenish sour and acid secretion would usually be removed before each washing, which was always kept up until the returning fluid was absolutely clear. It has been said, and I believe rightly, that incomplete lavage does more harm than good, really increasing, as it does, the irritation.

How a stomach with two openings, the patent pylorus and a working gastro-enterostomy more than 2½ inches in width, for I always make a large opening, and at the most dependent part of the stomach, could become so distended with fluid is more than I can comprehend. Naturally, I first thought of obstruction due to a kink in the jejunum, but this was quickly eliminated for two reasons: The bowels acted daily, and when purgatives were administered visible evidence of them was had in the stools very quickly. Moreover, the gastric contents, expelled voluntarily and withdrawn by the tube, showed, at no time, the slightest trace whatsoever of feces, but little bile, and consisted almost wholly of altered gastric secretion. It was highly acid, thin, and as green as grass. Gallons of sterile water were used at each lavage before the fluid returned perfectly clear.

I made no attempt to bring on convulsions by practicing Trousseau's, Erb's and Chvostek's methods of doing so. The diagnosis was plain enough, and the spasms when they came of themselves were too painful to reproduce unnecessarily. I was too glad to see them disappear even to consider doing anything which either intensified or made them more frequent.

While, as already indicated, it is my belief that every case of gastric tetany demands immediate surgical treatment, as in this way only can the dilatation, which is consecutive to pyloric stenosis, be effectually overcome, I am also of opinion that too optimistic statements have been made concerning both the immediate and remote effects of surgical intervention, as the most *severe cases may be fatal in spite of it. In those denominated* as of the third degree by Trousseau, in which the muscles of the pharynx, larynx and tongue, in addition to the musculature of trunk and limbs are involved, it seems reasonable that nothing can be depended on to give relief. My case plainly indicates that tetany may supervene eleven days after a perfectly satisfactory drainage operation has been done, and that it may yield to thorough and repeated gastric lavage with rather full doses of antispasmodics. In conjunction with the above treatment the withdrawal of all starchy, saccharin or other food likely to cause fermentation, should be rigorously insisted on. In the mildest cases of the first degree, in which the spasms are limited to the muscles of the fingers, hands and forearms, and there are no decided toxic manifestations, careful feeding, purgation and gastric lavage may suffice; but, with greater evidences of *toxemia* and *an extension of the tetanic* spasms to all of the limbs, trunk and head, a further postponement of surgery seems unwise and will, perhaps, lead to a fatal result. Buttermilk was the ideal nourishment in the case here reported. Everything else apparently caused fermentation, soon followed by nausea, eructations and vomiting, conjoined with depression and evidences of *general toxemia.*

I would refer those especially interested in the literature of this subject to the able and exhaustive articles by Warbasse,[2] Cunningham,[3] and John Young Brown.

Beginnings of Surgery.—The commencement of surgery dates from the moment when instruments of daily use, the weapons of civilization, were used as means of healing. Such were, in earliest times, flints, thorns, splinters of wood, shells, fishbones, pointed bones, teeth, horns, etc. With such means foreign bodies could be extracted, abscesses opened, scarification and blood-letting performed. To the instruments of daily life were added its manipulations as assistance to the art of healing; for instance, the means of mending broken weapons served as a pattern for primitive treatment of fractures.—Neuburger, History of Medicine.

THE EFFECT OF TARTRATES ON THE HUMAN KIDNEY *

WILBER E. POST, M.D.
CHICAGO

In *1912* Underhill[1] published his discovery of a severe form of renal degeneration or "nephritis" in rabbits and dogs produced by the subcutaneous administration of sodium tartrate. This publication was followed by three papers regarding experimental tartrate nephritis by F. P. Underhill, H. Gideon Wells and Samuel Goldschmidt.[2] Their observations are to the following effect:

1. Nephritis with impairment of renal secretory activity and extremely severe degeneration or necrosis of the convoluted tubules may be caused by the subcutaneous administration of less than 0.5 gm. of sodium tartrate to phloridzinized fasting rabbits weighing from 2,000 to 2,500 gm. The lesions seem to involve only the tubular epithelium, the glomerules being practically unaffected.

2. In similar manner nephritis may be caused by tartrate in somewhat larger doses when administered to fasting animals without phloridzin.

3. Rochelle salt administered by mouth to fasting animals causes nephritis: 8 gm. given to a 1,660-gm. rabbit caused fatal result; 5 gm. given to a 1,480-gm. rabbit caused no apparent ill effects; but histologic examination of the kidneys showed granular degeneration of the epithelium of the tubules.

4. When tartrates are given by mouth to well-fed rabbits, the salt is not so toxic as when similarly administered to fasting animals. In fact, after the administration of 1 gm. of Rochelle salt to a well-fed rabbit weighing 2,000 gm. the urine increased from 54 c.c. to 150 c.c. in twenty-four hours.

5. Sodium carbonate, sodium acetate and sodium citrate in quantities sufficient to maintain alkalinity of the urine in a fasting rabbit (2 gm. per day) cause no renal changes.

6. When the subcutaneous administration of tartrate *in small doses (0.5 gm. tartaric acid per kilogram)* is accompanied by the administration by mouth of sodium carbonate or sodium citrate, the renal changes are not so pronounced as without the alkalinizing salts. When large doses of the tartrate are given the alkali proved beneficial, as shown in the nitrogen elimination and in the histopathology of the renal tissues.

Shortly after these papers were published there also appeared a paper by Pearce and Ringer,[3] which corroborated the results described above, and called particular attention to the fact that in dogs the renal injury may be reduced by the production of a diarrhea by the tartrates, which prevents their absorption.

As expressed by the first-named authors, particular interest in the investigation of the influence of tartrates on kidney structure and kidney function is due to the wide-spread employment of tartrates in articles of diet, and the general employment of Rochelle salt as a purgative. The question was suggested by Dr. Wells: Are there injurious effects produced in the human subject, especially in nephritis, by the use of tartrates? The question is made more pointed by the suggestions of Fischer[4] in his works on edema and nephritis, that t trates reduce edema, and may relieve nephritis.

Observations were accordingly made on seve patients in the service of Dr. Frank Billings and oc pying the Sprague Institute beds in the Presbyter Hospital. Potassium and sodium tartrate was given mouth to ordinarily well-fed adults. The dose v from 1 to 6 drams, the average dose authorized by U. S. Pharmacopeia being 2 drams. Each voiding urine was put into separate clean sterile bottles a placed at once in an ice-box. The test for albumin v by the use of acetic acid and potassium ferrocyan The hydrogen ion concentration was determined, some of the cases, by means of indicators. The resu of a few of the observations are summarized in following protocols:

Case 1.—C. S., man, aged 57. Moderately advanced arte sclerosis. Urine examinations:

December 31, 1912, noon: No albumin.
4 p. m.: Sp. gr. 1.011; *faint trace nucleo-albumin; oc* sional hyaline and hyalogranular cast, occasio leukocyte. Reaction neutral to paranitrophenol.
Jan. 1, 1913, 2:40 a. m.: Sp. gr. 1.009; *faint trace ser albumin*; sediment same. Reaction neutral to metl red.
6 a. m.: *Rochelle salt,* 2 drams given.
10:30 a. m.: Sp. gr. 1.013. *No albumin.* Few cas Reaction neutral to rosolic acid.
2 p. m.: Sp. gr. 1.015. *No albumin.* Sediment sa Neutral to rosolic acid.
6:30 p. m.: Sp. gr. 1.015. No albumin. Sediment sa Neutral to rosolic acid.
January 2, 3 a. m.: Sp. gr. 1.015. *Faint trace nucl albumin.* Sediment same plus numerous spermatoz reaction same.
7 a. m.: Sp. gr. 1.015 *Faint trace nucleo-albumi* occasional hyaline cast; neutral to rosolic acid.
12:15 p. m.: Sp. gr. 1.007; *distinct trace serum albumi* occasional hyaline cast; neutral to rosolic acid.
4:50 p. m.: Sp. gr. 1.007; *faint trace nucleo-albumi* occasional hyaline cast; neutral to rosolic acid.
January 3: Seven specimens; two showed faint tr nucleo-albumin, others no albumin. All neutral rosolic acid; sediments same as above.
January 4, 5 a. m.: Sp. gr. 1.010. No albumin; sedime same; neutral to methyl red.
6 a. m.: Rochelle salt. Three drams given; four spe mens urine voided during day; none showed albumi sediment same; all neutral to rosolic acid.
January 5 and 6: No albumin in any specimen.
January 9, 3 a. m.: Faint trace nucleo-albumin; oth specimens during day showed no albumin.
January 10, 2 a. m.: Sp. gr. 1.004; no albumin.
6 a. m.: *Rochelle salt,* 6 drams.
6:30 a. m.: Sp. gr. 1.002. *Distinct trace nucleo-albumi* other specimens during day showed no albumi sediment remained about same.

Case 2.—G. K., man, aged 37. Acute bronchitis.
Nov. 12, 1912, 3:30 p. m.: Sp. gr. 1.021; faint trace nucle albumin. Sediment; urates ++, occasional cylindroi
November 13, 11:35 a. m.: Sp. gr. 1.018; faint trace nucle albumin; numerous cylindroids.
4 p. m.: No albumin.
November 16, 6 a. m.: *Rochelle salt,* 2 drams.
1:50 p. m.: Sp. gr. 1.015. No albumin. Sedimen numerous cylindroids.

Case 3.—Mrs. E. P. Hysteric hemiplegia, right-sided pye itis *(interval).*
Nov. 22, 1912, 8:50 p. m.: Sp. gr. 1.008; faint trace nucleo-albumin sediment; moderate number of leukocytes; bacilli, neutral to rosolic acid.

6 a. m.: Rochelle salt, 2 drams.
9:25 a. m.: Sp. gr. 1.005; faint trace nucleo-albumin; sediment same; neutral to rosolic acid.
2 p. m.: Sp. gr. 1.012; tests same as at 9:25 a. m.

Case 4.—G. A., man, aged 29. Acute bronchitis.
Dec. 1, 1912, 6:15 and 8:15 a. m.: No albumin; few mucus threads; occasional leukocyte.
December 2, 4 and 6 a. m.: No albumin; sediment same as above.
6 a. m.: *Rochelle salt*, 2 drams.
10 a. m.: Faint trace albumin; numerous cylindroids; no casts.
1 p. m.: No albumin.
December 5, 6 a. m.: *Rochelle salt*, 3 drams.
7 a. m.: No albumin; sediment same as above.
2 p. m.: No albumin; sediment same.

Case 5.—H. K., man, aged 19. Lumbago; tonsillectomy.
Dec. 12, 1912, 2 a. m.: Acid to litmus; distinct trace albumin; few hyalogranular casts.
6 a. m.: Acid to litmus; no albumin; hyaline threads; occasional cast.
6 a. m.: *Rochelle salt*, 3 drams.
10:45 a. m.: Neutral to rosolic acid; distinct trace albumin; rather numerous leukocytes; occasional cast.
5:30 p. m.: Neutral to rosolic acid; very faint trace albumin; occasional cast.
7:40 p. m.: Neutral to rosolic acid; no albumin; sediment same.
December 13, 3:20 a. m.: Neutral to methyl red; faint trace nucleo-albumin.

Case 6.—T. R., man, aged 19. Acute tonsillitis.
Dec. 26, 1913, 6 a. m.: Sp. gr. 1.022; neutral to paranitrophenol; faint trace albumin; urates and calcium oxalate crystals.
11:30 a. m.: Practically same findings except no crystals.
8:30 p. m.: Sp. gr. 1.020; other findings same.
December 27, 6:30 a. m.: Sp. gr. 1.030; faint trace albumin; urates +.
6:30 a. m.: *Rochelle salt*, 3 drams.
1:50 a. m.: Sp. gr. 1.022; neutral to paranitrophenol; faint trace albumin; urates +.
3:55 p. m.: Sp. gr. 1.028; neutral to rosolic acid; no albumin; occasional cylindroid and hyalogranular cast.
December 28, 6:30 a. m.: Sp. gr. 1.003; neutral to methyl red; faint trace nucleo-albumin and serum albumin.
10:20 a. m.: Sp. gr. 1.018; neutral to paranitrophenol; no albumin.

Case 7.—J. F., man, aged 32. Osteo-arthritis. Was in hospital Dec. 8, 1912, to Nov. 19, 1913. In March, 1913, urinalysis showed no albumin or casts. In May, 1913, he had a rather prolonged attack of diarrhea with severe abdominal cramps and from three to six stools per day. June 3, 1913, the legs and scrotum were markedly edematous and there was free fluid in the abdomen and fluid in the right chest. Urinalysis showed a large amount of albumin and many hyaline and granular and epithelial casts. From August 11 to August 18 Rochelle salt, 2 drams, was given every morning, and from Sept. 3 to Nov. 11, 1913, the same dose was given every morning and sometimes another similar dose given in the evening. Although the case had seemed almost hopeless, the patient left the hospital much improved, with no fluid in chest or abdomen and very little swelling of the feet. The urine still contained a large amount of albumin and few casts. While one cannot say how much, if any, of his improvement was due to the Rochelle salt, yet he improved more after it was given than before. It certainly seemed not to harm him, although given over a long period.

Two patients with nephritis of pregnancy seen at St. Luke's Hospital with Dr. C. E. Paddock were given cream of tartar or Rochelle salt regularly. One case entirely cleared up before termination of pregnancy and the other showed marked improvement, and these results were very satisfactory from the clinical point of view. These are cited, not to describe the plan of treatment in nephritis or even to give evidence of any benefit of tartrates, but to show that the administration of tartrates, even in nephritis, is not inconsistent with good clinical results.

These illustrations are typical of conditions and results which were obtained in other instances. 1. They give no evidence indicating that potassium and sodium tartrate in ordinary doses given by mouth in the human subject will cause albuminuria or cylindruria. 2. There is no evidence to show that tartrates aggravate an existing nephritis. 3. The acidity of the urine, indicated by the hydrogen ion concentration, was as a rule less after the administration of tartrates.

These findings are entirely consistent with the results of Underhill, Wells and Goldschmidt, for the smallest toxic dose administered by mouth to the well-fed rabbit (2,800 gm.) was 10 gm. Rochelle salt. This would be equivalent to 6.7 ounces in a man weighing 150 pounds. Large doses of Rochelle salt would, of course, have an important element of safety in their cathartic action, which would prevent absorption, as Pearce and Ringer observed in dogs. Administered subcutaneously, the smallest toxic dose was 0.5 gm. per kilogram, or about 1 ounce in a man of 150 pounds. In the first place, it is hardly conceivable that 6.7 ounces of Rochelle salt would be administered by mouth to a patient; and in the second place, it should impress on us the increased toxicity of medication administered subcutaneously or intravenously. When tartrates are given in a certain sublethal dosage, Underhill, Wells and Goldschmidt further noted that the urine of animals becomes pale, alkaline, and larger in quantity, which conforms in the first two respects to our own observations in man.

122 South Michigan Avenue.

CHRONIC ARTHRITIS

LINDSAY S. MILNE, M.D.
KANSAS CITY, MO.

Few diseases are the subject of greater confusion than those of the joints. Cases of chronic arthritis are so common, so distressing to the patient and so rebellious to treatment, that their study is one of the greatest interest and importance. Yet we find that in any work dealing with arthritis, the subject is most conflicting and uncertain. A whole series of diseases seem inextricably mixed up under the same name, or a variety of designations are applied to the same disease. Such names as "arthritis deformans," "rheumatoid arthritis," "chronic arthritis," "chronic rheumatism," "osteo-arthritis," "rheumatic gout," "infective and toxic arthritis," etc., are all indiscriminately applied to numerous affections of the joints, and to different stages of the same disease.

This confusion, as well as the number of theories which are prevalent in most works on this subject, indicate a very imperfect knowledge of this group of diseases, a condition which is almost natural considering the great technical difficulty attending the study of their pathology.

It is difficult to find any satisfactory terminology which will include all the various types of arthritis. "Arthritis deformans," for instance, is a common term applied to this group of diseases, yet if deformity be waited for before diagnosing the disease, the patient may become a hopeless cripple in whose case treatment may be of little avail. Similarly, the term rheumatoid arthritis" has become so entrenched in literature that it has come to represent a more or less definite clinical picture; yet as a precursor of chronic arthritis of any type, acute articular rheumatism is neither invariable nor even common.

To make any clinical or pathologic classification of arthritis is most unsatisfactory, as gradations occur between all types, and almost any variety may have a number of possible etiologic factors.

An etiologic classification is equally confusing as each causative agent may be associated with a great variety of pathologic types. Also the etiology of the many forms of arthritis has long been a subject of inconclusive discussion, and even at present the most speculative and unsubstantiated views are entertained. It is essential therefore before there can be any satisfactory classification or treatment of arthritis, that its etiology and pathology must be thoroughly understood.

At the outset of the study of chronic arthritis one must first be certain of the diagnosis of the disease. It is by no means uncommon to see cases considered and treated as arthritis which are not related to this condition at all. Cases of injury of the joints are frequently confused with arthritis, and in these cases, as in all studies of arthritis, roentgenoscopy is of the greatest diagnostic value. Not uncommonly the pains over the shoulder in various gallbladder, liver and diaphragmatic conditions simulate arthritis; so also the pains in the hips in prostatic and pelvic diseases, and in sciatica. Again, gout may cause great swelling of the joints, and its recognition and appropriate treatment is necessary before it can in any way be improved. Similarly, it is by no means uncommon to see cases treated as some other disease, such as tuberculosis of the joints, which are in reality the much less serious condition of what is generally known as rheumatoid arthritis.

In the investigation of the etiology of chronic arthritis one is faced with the great multiplicity of types which this disease may assume. In some cases there may simply be a chronic synovitis with or without effusion into the joints. In others the opposing bones become united by fibrous or bony ankylosis, while in other cases all kinds and grades of deformity may be produced. Are all these types related to different etiologic factors. or may any one infective process in different degrees of virulence and duration be responsible for the production of a variety of types of arthritis?

The most simple type of chronic joint-disease is that which is observed in old age. Here the joints simply become stiff, and often somewhat painful on movement. Often there is a moderate degree of musculature contracture which may limit still more the movements of the joints. These contractures are largely due to muscular wasting and occur particularly if the subject has been bedridden for a considerable time. They may, however, further the impression that there is an advanced chronic arthritis. In young, very emaciated subjects dying from some wasting disease such as phthisis, this stiffness of the joints and contractures resemble the condition seen in extreme old age, and may be very misleading.

DEGENERATIVE ARTHROPATHY

In a series of two hundred necropsies in elderly persons I found that in practically every case, when old age sets in, the cartilage of the joints participates in the general atrophy of the tissues. These changes occur independently of arteriosclerosis, or are associated with it only so far as arteriosclerosis assists in producing the general body atrophy. Degenerative changes in the joints are found with equal frequency in aged subjects, whether arteriosclerosis is marked or not. These atrophic changes in the joint-cartilage are found as commonly in women as in men. Indeed, the joints show degenerative changes in women at an earlier age than in men, as the atrophy of the internal organs is more marked and occurs earlier in women. Even though a man has hands gnarled by hard work the atrophic changes in his joint-cartilage may not be worse than are found in many women who have never seemed to have any joint-trouble. In the joints of all senile subjects there occurs a simple atrophy of the cartilage, chiefly in the situations normally most exposed to friction, and possibly also where nutrition is poorest. In the lower end of the femur there commonly is found a patch of cartilage degeneration on the anterior surface between the condyles and also in the center of the under surface of both condyles. In older subjects, however, the entire surface of the cartilage may become villous. These appearances are due to an atrophy of the cartilage. This process commences on the surface. The cartilage shrinks and tends to become fibrillated. In parts the surface of the joint may come to appear as if the underlying bone were covered only by a thin layer of fibrous tissue. This atrophic process generally takes place very irregularly, beginning at the surface and extending vertically along the lines of the cartilage cells. This irregular process accounts for the villous appearance of the cartilage so commonly observed. In the later stages, when the general atrophy of the body and the atrophy of the joint-cartilages are very marked, the cartilage may in parts completely disappear, uncovering the underlying bony structures. When the bone becomes exposed to the friction of the opposing joint-surface it tends to become thickened and eburnated. In these cases there is apt to be considerable pain on movement of the affected joint.

In the upper end of the tibia similar changes are apt to occur, although not so marked as in the lower end of the femur. The joint-surface often is observed villous in appearance, and in parts the underlying bone may have become extremely fibrillated and frayed out at their inner margins. In extremely old atrophied subjects the semilunar cartilages may become so fibrillated and atrophic that they can hardly be recognized. The articular surface of the patella is particularly subject to degenerative changes, and its entire surface may come to have a villous appearance, while the rest of the cartilages in the knee-joint are but slightly involved. The elbow-joints also usually show well-marked changes in old age. Patches of degeneration are common in the middle of the convexity of the lower end of the humerus, and the cartilage may be seen to be receding from the periphery of the articular surface. This recession is particularly evident on the head of the radius, where commonly only the center of the articulating cup may be covered by cartilage. The concavity of the olecranon in its middle part always shows a marked atrophy, and appears as if a band of fibrous tissue of varying width separated the articular surface into two equal parts. Fissures where the cartilage is atrophied in other situations in this joint-surface are also frequently observed, although the atrophy in the center of the concavity is always very marked before these become evident. In these atrophying conditions the cartilage becomes fibrillated and finally disappears. It may, however, become calcified or replaced by bony tissue. In all the joints somewhat similar changes occur. In the acetabulum, for example, the cartilage in the center of the concavity atrophies from the attachment of the ligamentum teres outward, till in many cases as much as one inch in diameter is covered by fibrous tissue only.

In these cases of senile atrophy there are no inflammatory changes associated with the process, as no evidences of inflammation in the synovial membrane or the marrow-spaces under the cartilage can be found. The condition follows on similar processes which cause general tissue atrophy in old age, possibly on defective nutrition. It is, therefore, not a real arthritis, but is perhaps better styled a degenerative arthropathy.

Similar changes are found in the joints of subjects who have died from chronic diseases associated with marked wasting, and consist essentially of an atrophy of the cartilage associated with no inflammatory changes. Such patients often complain of pains and stiffness in the joints, and a mistaken diagnosis of arthritis is not uncommonly made.

ETIOLOGY OF ARTHRITIS

True arthritis is essentially an inflammatory process, and its effects depend on the quality of the damaging agent, its duration and its method of extension to the joint. The same cause may thus give rise to vastly different forms of arthritis, and the mistake must not be made of necessarily classifying similar types in the same etiologic group.

Arthritis occurs in the course of numerous general infections, many of which seem to have a special selection for the joints. In typical acute rheumatism there is a rapid, although shifting and comparatively transient involvement of the joints. Infections with a great variety of organisms, such as gonococci, many strains of streptococci, staphylococci, occasionally pneumococci, typhoid bacilli, *Bacillus coli,* and others may present arthritis as their most prominent clinical feature. In many acute diseases such as diphtheria and the exanthems, arthritis may occur, yet, as also found in endocarditis occurring in these cases, some intercurrent infection, in many cases streptococcal, may be responsible for the associated joint changes.

It is also asserted that various defects of metabolism are associated with the dissemination of toxic substances which are capable of exciting inflammatory changes in the joints. This, however, is really only suggestive and has by no means been proved, as these toxins have not been determined. It is also more probable that the digestive disturbances which so frequently go along with arthritic cases are due to the same general infection which has damaged the joints, or that the abnormal intestinal condition admits of the dissemination of bacteria into the circulation, and in this way infects the joints. In this connection it is not uncommon to find that in many cases of dilatation of the colon there is an associated bacteriemia, particularly of the *Bacillus coli* and streptococci, these organisms being often also readily isolated from the urine. In the history of a case of chronic arthritis it is suprisingly frequent, almost universal, to find such conditions as chronic pharyngitis, tonsillitis, pyorrhea alveolaris, endometritis, nasal sinus infection, mastoiditis, chronic gonorrhea, chronic phthisis, or some other existing septic focus which may have important relationship to the etiology. Certain of these infective agents may act in some form of irritative toxins in the same manner as gout, in which uratic crystals are deposited in the cartilage, and may sometimes excite secondary inflammatory reactive changes in the synovial membrane and marrow-spaces subjacent to the joint cartilage, and so produce a true arthritis. In the bulk of cases, however, the inflammatory changes, which can invariably be observed, are due to a lodgment of bacteria in the joint structures. As a further clinical proof of the infective nature of arthritis deformans, it is by no means uncommon to find some swelling of the lymph-nodes and enlargement of the spleen. These are particularly evident in those cases of chronic arthritis affecting children, generally known as Still's disease.

Arteriosclerosis has been held by many to be a direct cause of arthritis, yet numerous cases are observed without any marked arteriosclerosis. The latter condition undoubtedly may be produced by the same factors which are also causing arthritis, but it has no direct bearing, as some assert, on the production of joint inflammation. Microscopic sections of joints in arthritis deformans cases do not, as a rule, show arteriosclerosis, and the condition does not seem to depend on any decreased blood-supply from the larger arteries of the bone-marrow.

Similarly, without any conclusive proofs either therapeutic or pathologic, it has been stated that arthritis deformans cases depend on a deprivation from the system of lime-salts.

PATHOLOGY

The milder grades of joint-infection, such as occur in rheumatic fever, cause an inflammation in the synovial membrane, and generally some effusion of serum into the joint and periarticular tissues. There is usually seen some slight congestion of the vessels in the marrow-spaces just underlying the joint-cartilage, giving to the joint-surface a somewhat pinkish color; but only rarely is the cartilage damaged in any way. As a rule, one might say invariably, in acute rheumatic fever due to the specific organism of that disease, this resolves completely, and chronic synovitis and persistent effusion do not result as in the more severe forms of arthritis. In other infections—*Streptococcus pyogenes,* gonococcus, etc. — the same course may be taken and result in complete recovery. Even purulent effusion may occur, and yet the joint may suffer no permanent damage.

In animals (I have used for this purpose rabbits and dogs), the joints may be injected with organisms of low-grade virulence, *B. coli* after prolonged cultivation, for instance, and slight or marked effusion may be produced. The synovial membrane is inflamed and the effusion from this is apt to be serous and soon disappears. In other cases, when organisms of greater virulence are used, the effusion may be purulent. Extensive purulent effusion may distend a joint for a considerable time, and yet the joint cartilage may remain undamaged.

When the infective agent is still more virulent, marked changes in addition are found in the cartilage. The vascular structures underlying the cartilage become engorged, giving a reddened appearance to the cartilage, and serum may be exuded from them through the cartilage toward the joint. The cartilage-cells along the lines of the exudation of the serum from the subjacent vessels become swollen and disintegrated, and their capsules distended. In other degenerated areas produced in this way leukocytes and granulation-tissue rapidly extend toward the surface of the cartilage, and should the irritant continue in unabated virulence, the cartilage at these points soon becomes destroyed and replaced by granulation-tissue. In the severer types of infection the entire joint-surface may be involved. In the milder varieties, however, the process tends to be more localized. A common appearance is to find after ten days or so that the fluid in the joint, previously purulent, is clear and the synovial membrane is congested and villous in appearance. This may be the only change. In other cases, however, the cartilage in several spots is apt to be pitted, where granulation tissue has extended upward from the subcartilaginous vascular structures.

Certain observers of arthritis in human cases have considered that simultaneously with these subcartilaginous changes destroying the cartilage, there occurred an extension of granulation-tissue from the inflamed synovial membrane at the periphery of the articular surface, and this pannus, spreading over the cartilage, destroyed it as it advanced. This, however, so far as I have observed, is in relatively small amount in experimental infections of joints in animals, and with no degree of certainty can be noticed in human cases.

In human cases of arthritis I have observed much the same pathologic changes to occur as can be produced experimentally in animals, the intensity and duration of the damaging agent being responsible for the many types which are encountered clinically.[1] Acute infections may, therefore, be found resulting in a synovitis with slight or large effusions into the joint cavity. This fluid may be serous, yet in other types of infection may be purulent. This may completely resolve and leave a normal joint, sometimes even if there has been extensive purulent effusion. In other cases chronic synovitis results, the joint synovium becoming thickened and villous with the frequent outpouring of fluid into the joint or a permanent effusion. Some of these hyperplastic villi may eventually become cartilaginous and some may break loose into the joint and form the loose bodies so commonly found in these cases. With even marked chronic synovial inflammatory changes the cartilage may still remain undamaged. In the more severe infections the cartilage may be, in whole or in part, destroyed, depending on the intensity and duration of the infection and the amount of inflammatory changes induced in the subcartilaginous marrow-spaces. The cartilage is destroyed in front of the inflammatory proliferation extending from a comparatively narrow layer of inflamed marrow-spaces immediately subjacent to the cartilage. The cartilage thus, in part or altogether, may become replaced by fibrous tissue, which also may unite with similar productions of fibrous tissue on the articular surface of the opposing bone and so produce adhesions, particularly if no excessive fluid separates the joint-surfaces, and movement be limited. It is in this way that the adhesive types of chronic arthritis are produced. These adhesions may naturally be localized to a few spots, or may be distributed uniformly over the entire articular surface. Secondary changes in this new tissue are also possible, although generally the process remains stationary at the fibrous adhesive stage. Bone and even cartilage formation may, however, occur, and eventually the joint may be obliterated by complete osseous union between the opposing bones.

The earlier stages of the less acute, progressive forms of arthritis often appear as small depressions on the surface of the cartilage. These degenerated areas are generally associated with an inflammatory focus in the subjacent marrow-spaces. The primary agent causing this may originally have settled in this position in the epiphysis, or have extended through from the joint. These subcartilaginous inflammations are, however, commonly found some little distance away from the cartilage, which suggests that the primary involvement of the joint is, in many cases, from the direction of the epiphysis. The degeneration of the cartilage over these areas is probably due to some local interference with nutrition, but it may be produced in the same way, as can be observed to take place in acute arthritis, by the extension upward of exudates which destroy the cartilage.

The endosteal cells lining the marrow-spaces included in this inflammatory process tend to produce metaplastic changes. Cartilage formation is frequently observed in these areas. There may also be a transformation into an osteoid tissue, which eventually may become dense bone.

The inflammatory tissue in the marrow-spaces may often be seen to extend upward through the degenerated cartilage, and may spread out for some distance on the surface. In some other cases there is found a comparatively large portion of atrophic fibrillated edematous cartilage, and only a comparatively small focus of inflammation in the underlying marrow-spaces, which probably has been the primary condition.

The processes which lead to deformity of the joint are produced in much the same way as is the adhesive type of arthritis. These further changes which may lead to deformity depend on several factors. The damaging agent is generally of less virulence and applied to the joint over a longer period than is the case in the conditions responsible for the adhesive types of arthritis. Frequently repeated infection of the subcartilaginous bone-marrow spaces may accomplish the same result. The numerous grades of deformity are determined in any case by the cessation of the causal condition affecting the joint or its continuance in varied severity and duration. It is the gradually progressive destruction of the cartilage induced by inflammatory conditions in subjacent marrow-spaces, and the consequent proliferation of new cartilaginous and bony tissues, which eventually are responsible for the extreme deformities which are so commonly observed in chronic arthritis. Another factor which must not be neglected is the tendency of all the joint-structures, the synovial membrane, the cartilage, both perichondrial and hyaline, and the endosteal tissues in inflammatory and proliferative states, to metaplasia. In all cases of arthritis the synovial membrane shows considerable reaction. At first it is simply congested; later its lymphoid elements become hyperplastic and it assumes a villous appearance. Fibrous changes may occur in these villi, and finally cartilage or even bone may be produced. The loose bodies found in so many arthritic joints are chiefly composed of cartilage or bone, and for the most part are detached inflammatory metaplastic synovial proliferations.

Cartilage is thus more or less interchangeable with fibrous tissue in the joints. It is not uncommon to notice when the joint cartilage is becoming atrophied that it becomes calcified or transformed into a fibrillated structure closely resembling fibrous tissue. Also perichondrial fibrous tissue commonly becomes changed into typical hyaline cartilage. The deeper layers of the cartilage may also proliferate, forming large nodules of hyaline cartilage or bone. The greatest metaplasia, however, is found in the subcartilaginous inflammatory process, where bone or cartilage as a rule tends to be formed.

[1] Milne, L. S.: Chronic Arthritis, Jour. Path. and Bacteriol., 1911-1912, xvi, 195.

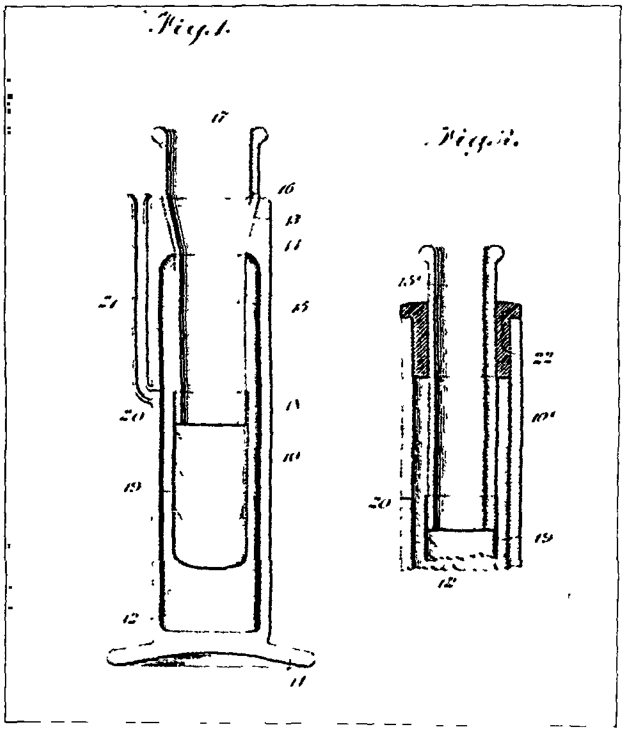
malignant test is obtained from a cancer of the uterus. *If such tissue is used, pregnant serums will at times* give an apparently malignant reaction because of the fact that pregnant serums will digest uterine as well as placental tissue (Lindig). It must be that the uterine cells in the tissue in such cases are digested instead of the cancer-cells.

Eleven known pregnant women reacted positively to the test.

Six of seven suspiciously pregnant women reacted positively. One of the six, as previously reported, denied the possibility, but admitted her true condition when informed that the blood-test showed what it was. An examination revealed a two and one-half to three months' pregnant uterus. The single negative reaction in this group is interesting in that the correctness of the negative finding was proved by operation. A woman presented herself at the hospital with a marked right-sided pelvic inflammation that required immediate surgical intervention. She also appeared on examination to be about four months pregnant. The pregnancy test was asked for, and run with a negative reaction. Operation revealed an extensive peritonitis (involving the right tube), which produced such a thickening of the pelvic parietal peritoneum that it was taken to be an enlarged uterus. The uterus, however, was non-gravid. There are two glaring errors in this set of cases. Two girls, possibly illegitimately five weeks pregnant, reacted positive, but later proved to be not pregnant. The blood was taken about 2 p. m. in each case and run that evening ready for the incubator. It is probable that amino-acids of digestion caused the error in each case. instead of faulty technic, as the placental tissue was carefully tested before use. Since these errors, which are Nos. 16 and 17 in my series, I have taken the blood, for diagnostic purposes, on an empty stomach in the early morning, with but a very few exceptions.

The positive findings in persons known not to be pregnant present an interesting subject for study. Lindig found that tumors of the genital tract caused the production of a ferment that was capable of digesting ovarian and uterine, as well as placental tissues. I have had three males with tumors of the genital tract that possessed a similar ferment, that is, a ferment that digested placental tissue. One of these cases, previously referred to, was a cancer of the testicle; and the other two were malignant papillomas of the bladder, one of which has been verified by microscopic section, the other by a clinical history, as already described. No male with a malignant growth elsewhere has produced a ferment that affected placental tissue in the least. The other cases, with positive reaction, though patients were not pregnant, were all in women with a questionable uterine history. Kabanow finds a similar selective action of ferments mobilized as the result of gastro-intestinal disturbances. Normal tissue is digested similarly to that diseased with a negative reaction to normal tissue from other portions of the digestive tract. The various sections of independent ferment production seem to be governed by the difference of functional activity. This selective action of certain ferments suggests the probability that the "protective ferments" of Abderhalden or the "antiferments" of Vaughan are produced by a group-cell activity of the tissue invaded. Whether it represents a dual action of the extracellular ferments or is produced independently by the cells for the one purpose, is open to discussion. In either case it suggests the possibility of being able to determine roughly the location of certain classes of tumor manifestations. These group reactions would seem to demonstrate that the blood-serum is in reality a means of conveyance rather than the place of production of the special ferments.

My work with the Abderhalden biologic test has impressed me with two sources of error when using the usual urinometer jar or large test-tube as an improvised dialyzing apparatus. One is the bacterial contamination of the thimble and its contents, when filling the thimble outside the dialyzing chamber. The second and more serious possible error is the danger of getting a drop or so of the blood-serum, or a speck or two of the protein material, on the outside wall of the dialyzing thimble. While the precaution of rinsing the thimble with distilled water before placing it in the improvised dialyzing chamber has always been taken, there necessarily remained an uncertainty as to the complete removal of the serum or tissue by such washings. In order to prevent these uncertainties, I have had made by Eimer and Amend of New York, and have used for some time past, the apparatus shown in Figures 1 and 2.



Figs. 1 and 2.—Two forms of apparatus for performing the Abderhalden serodiagnostic examination.

There is shown at 10 a container 1 inch in inside diameter adapted to be supported in upright position 5 inches high on a base (11) and of a preferably tubular cylindrical form. This container provides a chamber (12) into which the desired solution is to be placed. The upper end of the container is provided with a mouth which may be formed in the construction as shown in Figure 1, by an integral shoulder (14) ground on a preferably conical taper.

At 15 there is shown a combination stopper and funnel of substantially tubular form, having near its upper end an enlargement or shoulder (16) which is preferably ground on its outer surface to conform with the surface of the shoulder (14) against which it is adapted to be seated, making a substantially hermetic joint between the stopper and the container mouth. The upper end or mouth (17) of the funnel is normally open for the reception of protein and blood-serum to be used for the test, introduced into and through the funnel (15) to the attached thimble (19) at 18, which should have an outside diameter of 11/16 inches. The mouth (17) should be closed preferably by a cotton plug. Because of the definite connection between the funnel and container mouth, the thimble will be maintained at the proper level, and in a centered position with respect to the inner wall of the container and out of contact, therefore, with it.

The container is provided with a lateral opening (20) with the tubular extension (21) 1 inch below the shoulder for the dual purpose of equalizing the atmospheric pressure, and also of providing a means for introducing into the chamber (12) liquids at any time during the progress of the test without having to remove the funnel-stopper with attached thimble.

The form of apparatus shown in Figure 2 includes a container 10^1 of a simpler form than that above described. Instead, however, of providing ground connections immediately between the filling-funnel and the mouth of the container, a rubber gasket (22) serves the purpose of making a substantially air-tight seal for the chamber (12), and at the same time serves the purpose of maintaining the thimble (19) in spaced relation to the walls of the container and at a proper level in the solution contained therein. All the other features of the apparatus are identical with the description of Figure 1.

When the container has been filled with the required amount of distilled water and the parts assembled it is ready for sterilization with live steam, after which there is no part of the technic that requires or allows of the exposure of the outer surface of the dialyzing thimble, a feature readily recognized as a safeguard in performing the Abderhalden serodiagnostic examination. The necessary chloroform and toluol may readily be added to the sterile distilled water through tube 21 or hole 20 by means of sterile pipets. The top of 21 should be closed with a cotton plug in Figure 1. In Figure 2, hole 20 may be closed with a strip of adhesive plaster, which serves the added purpose of making a good place for necessary notations. Otherwise the technic of the test is the same as previously described by various writers.

REPAIR OF TENDONS BY FASCIAL TRANSPLANTATION

DEAN D. LEWIS, M.D., and CARL B. DAVIS, M.D.
CHICAGO

The free transplantation of tendons to repair defects in other tendons resulting from trauma or infection has become a well-recognized surgical procedure. The tendon of the palmaris longus has been used in most of the cases in which free transplantation has been attempted, for it can be removed without interfering with the function of the wrist or hand. When a number of tendons are to be repaired — for example, when the common extensor tendons of the fingers are to be repaired or when long defects exist in the tendons—enough material may not be supplied by the palmaris longus tendons and another source of supply for material for transplantation must be looked for.

Experimentally, it has been demonstrated that fascia behaves much like tendon when transplanted, and that long defects in tendons may be bridged by tubes of fascia; and that tendon, which cannot be differentiated from the tendon which has been destroyed, develops to repair the defect.

The repair of defects in tendons by means of fascial tubes has not been resorted to frequently in man, the direct transplantation of tendon having been attempted oftener. The following case is reported because an opportunity was offered later to examine the tendon which had formed within the fascial tube, and also to study the fate of the transplanted fascia.

History.—Dr. W. K., aged 32, was admitted to the Presbyterian Hospital, Jan. 26, 1913. Fourteen months before a patient had bitten the ring finger of his right hand. Soon a severe infection developed which necessitated removal of the terminal and a part of the middle phalanx of the ring finger thirteen days after the injury was received. Finally both the sublimis and profundus tendons were removed, the incisions continuing to discharge for two months after the first operation.

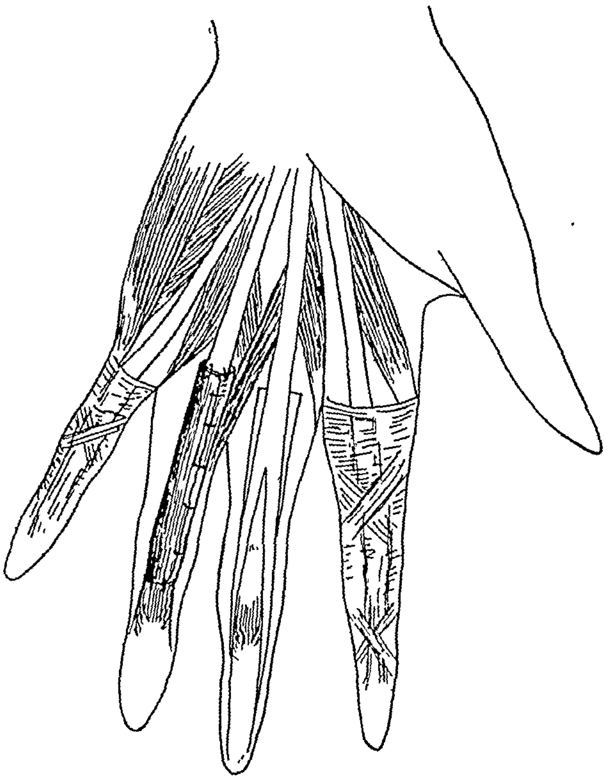


Fig. 1.—Diagrammatic sketch to show tube made from fascia lata which surrounds the proximal ends of the tendons and is attached distally to the periosteum. If the tendons are to be attached separately two fascial tubes are used.

Examination.—The terminal phalanx of the ring finger is absent. The end of the middle phalanx has also been removed, the bone lying close to the skin which seems, however, to be well nourished. On both the volar and dorsal surfaces of the finger are longitudinal scars which extend to the middle of the hand. The scar on the volar surface is somewhat hypertrophic. There is no flexion of the middle phalanx. The proximal phalanx can be flexed by the lumbricales and interossei. The skin on the volar surface is somewhat adherent at the site of the longitudinal scar, but it can be moved fairly well over the subjacent tissue on either side of it. In the middle of the palm of the hand, at about the transverse fold, there is some slight enlargement and resistance, which probably indicates the position of the retracted and attached ends of the flexor sublimis and profundus tendons.

Operation.—Jan. 27, 1913, an attempt was made to repair the tendons and prolong them to the end of the middle phalanx, part of which, as stated above, had been removed. An incision was made at the side of the finger and a volar flap was raised. Considerable scar tissue was found, but enough tissue could be carried up with the flap not to interfere with its integrity. The incision was carried through the interdigital fold into the palm, for the ends of the tendons were so adherent that considerable dissection was required to free the tendons in order that a fascial transplant might be inserted, so that when they contracted their action would be transmitted to the transplant and not expended on tissues adjacent to it. After the tendons were dissected free an incision was made into the thigh and the fascia lata was exposed. A strip of fascia measuring about 3½ inches in length and ½ inch in width was then removed, a thin layer of subcutaneous fat being left attached to the transplant. The fascial transplant was then placed back of the tendon, one end of the transplant was sewed around the tendons, and the other end was attached to the periosteum at the end of the middle phalanx. The surface covered with fat was placed so that it would form the inner lining of the fascial tube. This was done with the idea of furnishing to the tendon, which we hoped would develop, a layer of tissue which would permit of its sliding within the fascial tube. We hoped to reproduce much the same conditions that are found in the osteo-aponeurotic canals and synovial sheaths normally. After the fascial tube had been completed by a layer of fine chromic catgut sutures, which united the edges of the transplant anteriorly, the skin flap was sutured back into position with fine beeswaxed silk and a dry dressing was applied. No immobilizing dressing was used, for motion was desired and encouraged immediately after the operation.

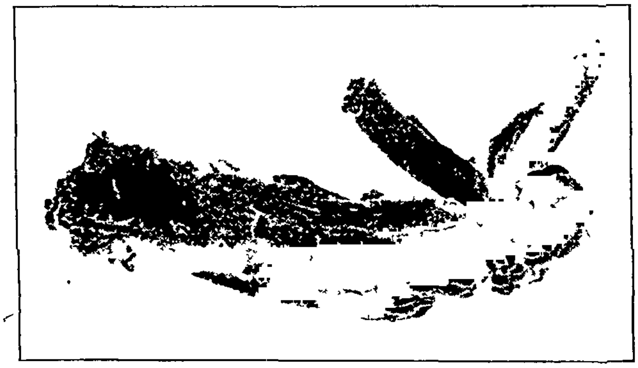

Fig. 2.—Tendon which formed following the operation. The finger was amputated 255 days after the fascial tube was inserted. The fascia remains intact, forming a sheath for the tendon which has developed from the proximal ends of the flexor sublimis and profundus tendon. The two tendons, separated by a thin connective-tissue septum, can be distinguished in the tube.

Result.—Active motion was so painful at first that not much was attempted until seven or eight days had passed. The patient reported occasionally after the operation. Within six weeks a definite rounded band, which rolled under the skin, could be felt. When flexion of the phalanx was attempted this band became more prominent, leaving the surface of the bone. When the band was held against the bone a greater degree of flexion could be obtained. Finally the middle phalanx could be flexed to about 80 degrees. As the patient was about to leave institutional work to enter private practice, he wished the finger removed for cosmetic reasons; the crippled finger, moreover, interfered somewhat with his work, notwithstanding that considerable improvement in function had followed the insertion of the fascial transplant. Oct. 9, 1913, the finger was removed under novocain anesthesia, the amputation being made through the head of the metacarpal bone. When the specimen was dissected a well-formed tendon was found. This differed from a normal tendon in the lack of luster only. In all other respects it resembled closely a normal tendon. When the tendon, which was about 3½ inches in length, was divided transversely, the original fascial tube could be seen. It contained tendinous tissue. Both the sublimis and profundus tendons had proliferated into the tube, for each tendon could be seen separated by a delicate fibrous septum. The newly formed tendon is represented in Figure 2.

Histologically the fascia is well preserved. The nuclei stain well and the bands of fibrous tissue are very similar to those found in normal fascia. Fascia when transplanted usually becomes somewhat edematous and infiltrated with leukocytes. These changes, however, occur early and after twenty-four days the transplanted can hardly be differentiated from normal fascia. The thin layer of subcutaneous fat transplanted with the fascia has disappeared and the newly formed tendon which has formed as the result of the proliferation of the tendons inserted into the fascial tube, is closely adherent to the transplanted fascia. The tissue filling the tube is tendinous in structure, well-developed bundles of fibrous tissue being separated by delicate connective-tissue septa. There is no histologic evidence that this tissue has developed from the fascial transplant. The transplant has apparently merely acted as a tube which has directed the growth of the proliferating tendons.

These findings are not in accord with those of Kornew,[1] which are based on experimental work on rabbits and dogs. He believes that, when a fascial tube is inserted between the cut ends of tendons, the fascia proliferates to form the tendon and very little of the new tendon is formed by proliferation from the ends of the divided one. The findings in the case which we have described would indicate that the fascial tube plays a passive rôle in the development of the new tendon. Experimental work has already demonstrated the value of fascial tubes in the repair and reconstruction of tendons. This method has not as yet been extensively employed and this case has been reported to show the functional and anatomic possibilities.

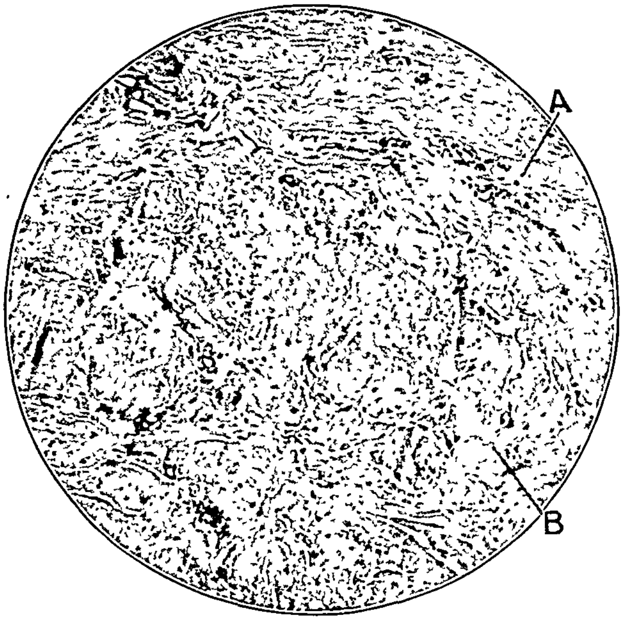

Fig. 3.—Cross-section of the tendon. The fascia, well preserved and appearing like normal fascia, forms a sheath for the tendon which has developed. There is no evidence that the fascial tube plays an active part in the formation of the new tendon. It forms merely a canal along which the tenoblasts of the divided tendons proliferate. A, section through transplanted fascia. B, section through new tendon.

As Rehn[2] has recently shown, some loss of motion occurs in transplanting flexor tendons into the fingers,

2. Rehn, E.: Klinischer Beitrag zur freien Sehnenverpflanzung, Arch. f. klin. Chir., 1913, cii.

because the transverse aponeurotic bands are lost The loss of these bands permits the tendon to leave the bone when the muscle is contracted, resulting in some loss of motion. This was indicated in the case reported, for a greater degree of flexion of the phalanx could be obtained by holding the tendon against the bone In one of Rehn's cases a ring was worn to accomplish this purpose.

Fascial tube repair of tendons offers much in plastic operations on the extensor tendons of the fingers There may be some limitation of motion after repair of the flexor tendons because of destruction of the transverse bands Besides the flexor tendons are closely grouped in the palm and there is a finer mechanical adjustment than there is in the common extensors

THE DIAGNOSIS OF SPINAL CORD TUMORS

WITH REPORT OF TWO CASES

HYMAN CLIMENKO, M D
Adjunct Visiting Neurologist to the Montefiore Home, Associate Visiting Neurologist Neurological Hospital
AND
DAVID FELBERBAUM, M D
Pathologist to the Montefiore Home and Hospital
NEW YORK

Through the wonderful advance in modern surgery, the spinal cord as well as the brain has become readily accessible, hence an early and accurate diagnosis of spinal cord tumors is of the utmost importance The only hope for permanent relief lies in the earliest possible removal of a new growth, before irreparable injury to the cord has taken place

The two following cases, which occurred in the services of Dr I Abrahamson, to whom we wish to express our indebtedness for the courtesy of observing and reporting them, are of great interest from this point of view. The first illustrates how syphilis not of the central nervous system may mislead one, while the second is peculiar in its onset and course

CASE 1—Mrs H S, aged 55, born in Austria, entered Montefiore Home Nov 17, 1911, complaining of pains and loss of power in lower extremities, loss of control of bladder and rectum, girdle sensation and tingling in lower extremities and right hand

History—The family history was negative except that the patient's mother had a wasting disease of many years' standing The patient was always of a delicate constitution and had convulsions in early childhood Her menstrual history was negative She married at 21 and had nine healthy children, no miscarriages At 25 she had a cystitis following childbirth Ten years before admission she suffered from a chronic ulceration of the legs Fifteen months before admission her present illness began and was insidious but progressive in its course She first complained of tingling and pulling sensations which began in the soles of both feet and gradually ascended to the hips A little later more or less constant pains developed about the middle of the spine, shooting downward into both legs, and later, stiffness and weakness of both legs appeared The weakness was immediately preceded by a girdle sensation in the lower part of the abdomen Three months after the commencement of her illness she could no longer walk Two months previous to admission she lost control of bladder and rectum A few weeks before admission she noticed a tingling sensation of the little finger of right hand No diplopia, headaches, vomiting or convulsions were present at any time When admitted the patient could neither stand nor walk. She lay on her back and could sit up only with great difficulty. Both lower extremities were flexed and extremely spastic

Examination—Double Babinski, Oppenheim, Mendel and Bechterew were present with double ankle clonus Both knee jerks were lively The lower abdominal reflexes were absent The various reflexes of upper extremities were normal Pupils reacted consensually to light, accommodation and pain Gross motor power of the lower extremities was greatly diminished and the movements were carried out sluggishly and painfully Passive movements were difficult to carry out because of the enormous spasticity The spine showed no deformities, but there was a marked hypersensibility to pressure at the tenth, eleventh and twelfth dorsal spines There was a slight hyperextension of the interphalangeal joints of the fingers The cranial nerves were negative, save for a slight asymmetry of passive innervation of the face, the right being stronger, this difference, however, disappeared on active or emotional innervation The lower extremities were covered with pigmented copper colored scars varying in size from a millet seed to a large pea Over the middle of the outer aspect of the left leg there was a scar of an old ulceration The feet were cold and cyanotic Decubiti were over both buttocks A sensory test taken in January, 1912, showed a loss of all three sensations from the level of the mammae, down anteriorly and posteriorly The sensory disturbances found in May, 1912, are best seen by the accompanying chart (Fig 1) Vibration sense was absent in the lower extremities Stereognostic sense was present

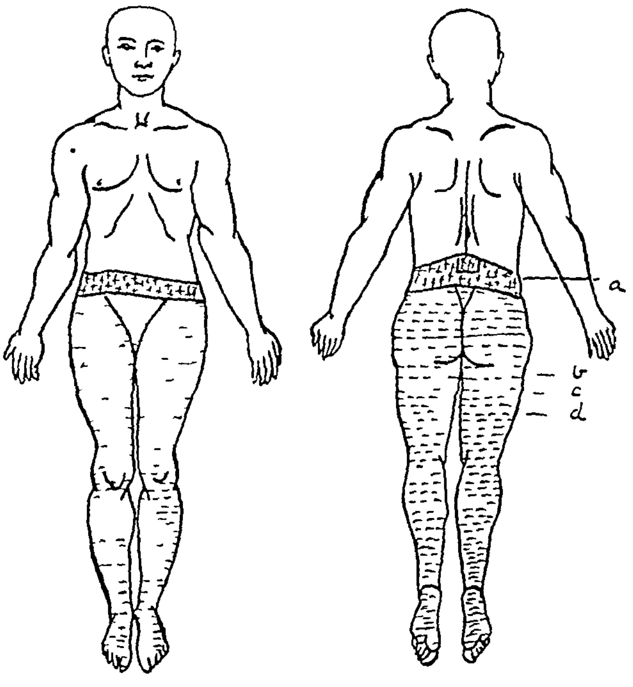

Fig 1—Chart of sensory disturbances areas found in Case 1 a, hyperalgesia, b, anesthesia, c, analgesia, d, thermanalgesia Rectangle in lower dorsal region shows location of extramedullary tumor

The heart was normal, pulse 78, blood pressure 150 mm systolic and 120 mm diastolic Blood serum, tested for the Wassermann reaction by Dr D M Kaplan and Dr D Felberbaum independently, gave a strong positive reaction The cerebrospinal fluid by Wassermann test at the same time, however, was negative The spinal fluid registered 30 cm by Nonne's apparatus, and was clear. Globulin reaction was positive Albumin in excess and 25 cells were present in 1 cm of fluid On these laboratory findings the patient was given two full doses of salvarsan intravenously, followed by many intramuscular injections of mercuric bichlorid The condition apparently improved a little, the level of the sensory disturbance became lower and there was some increase of motion

Diagnosis.—In analyzing this case, then, we have symptoms of compression myelitis, Wassermann plus reaction in the blood, and a slight improvement following a thorough course of antisyphilitic treatment. Therefore it is not at all surprising that a diagnosis of syphilis of the cord was adhered to for a long time. During May, 1912, however, after several very careful sensory examinations, a constant level was established. This, together with the symptoms previously described, especially taking into consideration the unbroken progress of the symptoms with their constancy, the decided tenderness over the spines of the tenth, eleventh and twelfth dorsal vertebrae and the narrow band of hyperesthesia above these vertebrae, conclusively proved that we were dealing with a constant lesion within the spinal canal, extramedullary, which was causing the compression, that is, a new growth and not a syphilitic process, in spite of the positive Wassermann and apparent improvement following treatment. An operation was therefore urged.

Operation.—June 14, 1912, Dr. Charles Elsberg removed an extramedullary tumor which was situated at the level of the ninth, tenth and eleventh dorsal vertebrae. The patient made a complete recovery from the immediate effects of the operation, but succumbed July 29, 1912, to the extensive decubiti and pneumonia.

Specimen.—The tumor was irregularly elliptical with a cauliflower-like surface, and measured ¾ by ½ by ¼ inches. It was situated between pia and dura being only moderately adherent. Histologically it proved to be a typical endothelium of psammoma type, probably arising from the pia. Permission was obtained to remove the spinal cord and at the level where the tumor had originally been located firm pia-dural adhesions were found (Fig. 2), and the cord was so completely compressed that it was divided into two parts, separated by a thin membrane, showing clearly the unfortunate result of prolonged compression and the impossibility of a restoration even after the removal of the cause.

Case 2.—Mrs. E. G., a widow, aged 52, born in Russia, entered Montefiore Home March 21, 1913.

History.—Her family history was negative. The patient had always worked hard. She had had one live child and one miscarriage; menstrual history negative. Her present illness began one year and three months before admission, was of a rather sudden onset with severe temporal and occipital headaches, which were more or less constant and increased on lying down. Time of day made no difference; she often would be awakened from sleep by severe headaches. Six months after onset of disease the right hand and arm began to grow weak and somewhat painful and swollen. Two months later the right leg began to grow gradually weak. This improved somewhat, however, while the right arm progressively grew worse. During the two months previous to admission the left hand and arm began to grow weak, and about the same time the patient began to complain of dyspnea, precordial pains, dizziness, and spots before the eyes. Finally the difficulty in breathing became so severe that she was unable to stand or walk. She soon completely lost the power of right arm and developed incontinence of the bladder and rectum.

Examination.—Patient half lying on her back, propped up with pillows. Dyspnea and cyanosis evident; respirations 40 per minute. Right Babinski present. Flexion of the left toe and extension of the others obtained by plantar stimulation on left side. Right ankle-clonus obtained; left ankle-joint reflex obtained with difficulty. Right knee-jerk and patellar jerks lively and stronger than left. Abdominal reflexes not elicited, possibly because of the position of the patient. Reflexes of upper extremities absent, including the scapula. Both corneal reflexes were present and pupils reacted normally to light and accommodation; they were moderately dilated. The patient could move both ankles, left better than right. Flexion and extension of knees were present, but left was better than right. All active movements of right hand were absent, in left they were clumsy and the patient could not execute any finer movements, could not move right shoulder, and there was no resistance whatsoever to all passive movements, the condition being that of complete flaccid paralysis. Direct myotatic irritability was absent, and the muscles were in a distinct hypotonic state. Atrophies with electrical changes of the intrinsic muscles of the right hand were distinct. A sluggish reaction to both currents was obtained in the left hand. The skin was cold and dry and peeling in some parts. Subcutaneous tissue apparently was in a myxedematous condition. Cranial nerves were negative with the exception of the right eighth, which showed a distinct diminution of both air and bone conduction. The sensory disturbances are shown in Figure 3. Blood-pressure was 165 mm. systolic and 140 diastolic. Heart and lungs were negative. Wassermann reactions in blood-serum and cerebrospinal fluid were also negative. Urine specific gravity, 1.025; albumin and casts were not found.

Diagnosis.—Various diagnoses were offered in the analysis of this case; chiefly among these were cardiorenal disease and arteriosclerosis of brain and spinal cord. One can readily see the reasons for such varied diagnoses, namely, the extreme dyspnea and cyanosis, palpable arterial changes with increased blood-pressure on the one hand, and the apparent hemiplegic type of paralysis with vague cerebral irritative symptoms such as are incidental to arterial changes on the other. Nevertheless, on close observation, the sensory findings, which were carefully charted and repeatedly found to be the same, together with the atrophies and trophic disturbances in the upper extremities, pointed toward an isolated segmental lesion in the cord. This was more emphasized by the absence of any objective cerebral symptoms, and the well-marked tenderness on pressure over the upper cervical vetebra and nape of neck, and an upper segment of hyperesthesia made it clear that here again we were dealing with a neoplasm of the cord. July 6, 1913 the patient died from symptoms of cardiac failure.

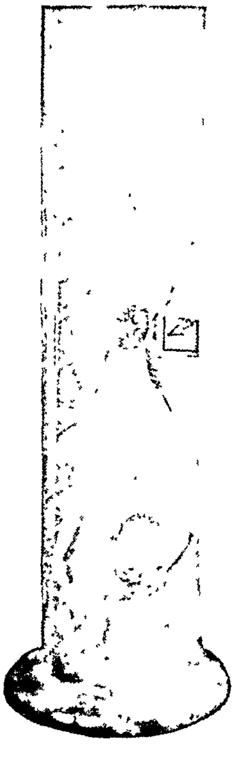

Fig. 2.—Extramedullary tumor removed in Case 1. Arrow points to growth.

Necropsy.—Dr. Felberbaum gave the following report in brief: Body that of a short, senile female. Fatty layer deficient. Pleural cavity free except for some adhesion over right apex. Pericardial fat increased, heart dilated. Mitral valves thickened, sclerotic and shrunken. Aortic valves thickened, and fatty atheromatous patches in aorta. Tricuspid valves normal, pulmonary valves thickened. Right ventricle and auricle much dilated and flabby. Heart muscles brownish; no hypertrophy of walls. Lungs congested. Subpleural hemorrhages on mediastinal surface of lungs with small ones on costal and diaphragmatic surfaces. Lung tissue dense, fibrotic and edematous. Liver, normal in size, with numerous patches the size of millet-seed immediately under the capsule. Liver substance very friable. Spleen very small; tissue dense but friable. Kidneys enlarged, cortex diminished and the capsule adherent in spots. Uterus small, endometrium thickened and polypoid. Gastro-intestinal tract negative. Brain normal in size, with well-marked convolutions; congestion present. Basilar vessels thickened and some plaque formation is seen.

When the brain was separated from the cord a brownish jelly-like substance was found replacing the region of the central canal of the lowermost portion of the medulla, and continuous with a similar condition of the upper part of cord. The cervical cord was enlarged throughout to about twice its thickness. This was caused by a new growth which occupied most of the posterior half of the cord, being especially extensive on the right, and replacing the commissures, the central canal, part of the anterior and posterior horns and columns. The growth is grayish, soft and well defined. It extends down to the seventh cervical segment, and is more centrally located at this point and much less in extent.

Histologic Examination and Diagnosis.—In the pons the structure greatly resembles exuberant granulation tissue with its distended and tortuous arterioles, edema and fibroblasts, with here and there some round-cell aggregations. This process is apparently located around the central canal, but no cells of a malignant nature could be found. The mass which corresponds to the new growth in the cord is composed microscopically of broken-down material. Along the posterior margin between the entrances of the posterior roots a narrow strip is found containing peculiar dark-staining cells, varying much in size and shape, showing mitosis and frequently assuming a column-like arrangement. Here and there giant multinuclear cells are seen. The pia in this situation is greatly thickened and the cells previously described are also found in the pia which is intimately connected with the cord. The blood-vessels are sclerotic, and many ganglion cells of the anterior horns show various stages of degeneration. In the lower part of the cervical cord where the pathologic condition is central, none of these peculiar cells can be found and the condition is merely an area of degeneration with edema and vacuolation, that is, beginning cavity formation. There only can the central canal be made out; it is dilated and tortuous. The diagnosis is gliosarcoma of cord with invasion of pia and in an advanced stage of breaking down.

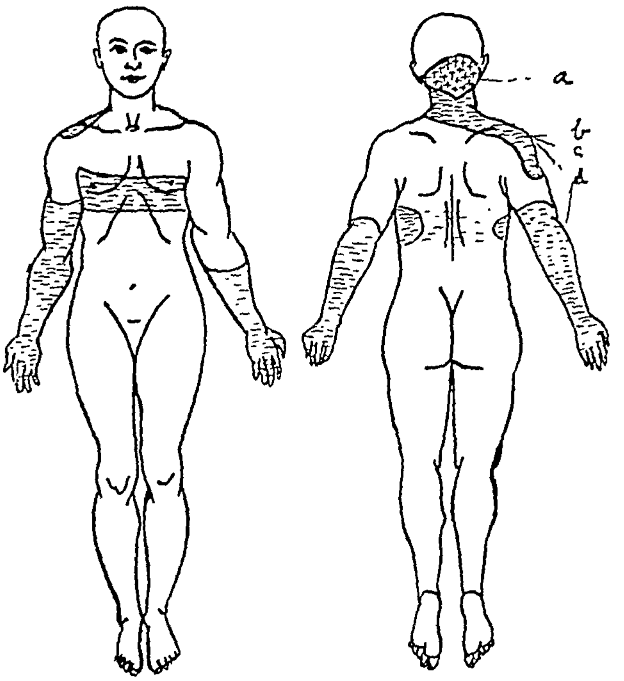

Fig. 3.—Chart of sensory disturbance areas found in Case 2. a, hyperalgesia; b, anesthesia; c, analgesia; d, thermanalgesia.

The diagnosis of extramedullary tumor of the spinal cord can be made early in the course of the disease, provided we obtain and interpret properly the subjective and objective symptoms. When these are correlated with our knowledge of the anatomy and physiology of the central nervous system we are able to locate the exact site of the growth, even in the incipient stage.

Tenderness over the vertebrae with various neuralgic symptoms that are persistent, usually unilateral and localized, preceded by paresthesia and followed by cramps and finally by atrophies, are, in order, the earlier symptoms of focal disease of the cord. If these can be ascribed to root irritation, from the presence of sensory disturbance, our suspicions should be at least aroused. Sherrington has demonstrated that a root does not supply a sharply defined area, but on the contrary the root areas overlap each other. Whereas in ordinary neuritis the sensory disturbances are confined closely to the course of the nerve, the disturbance caused by a root irritation is not sharply outlined, but will reach above and below the root area, gradually merging from the normal to the diseased. Furthermore, there is usually associated with the latter a band of hyperesthesia above the anesthetic zone.

Chief among other conditions that may give rise to similar symptoms is vertebral caries. The absence of tuberculosis elsewhere and a negative Roentgen-ray examination of the spine and lungs will permit of its exclusion.

Syphilis is always difficult to differentiate, particularly when the patient has a known syphilitic infection. Lues when affecting the cerebrospinal axis rarely confines itself to one locality, but is rather of a disseminated character. The symptoms are not constant but *vary considerably especially with treatment.* Syphilis can reasonably be excluded if the cerebrospinal fluid gives a negative Wassermann reaction, when a large quantity of the fluid is employed in the test (1 c.c.).

Reflex symptoms from a disease of a visceral organ may resemble the early symptoms of spinal-cord tumors, as aneurysm, neoplasm, etc. A careful analysis of the symptoms, combined with Head's zones and the absence of anesthesia, instead of root symptoms will exclude a cord lesion.

As the tumor grows it will compress the cord causing the appearance of tract symptoms. At first, if one-sided, these will commonly assume the type known as the Brown-Séquard syndrome, and if at this stage we can exclude syphilis, caries and multiple sclerosis localized in the cord, it is probable that a tumor is present. Here we wish to emphasize that when once a level lesion is established through a careful sensory study, though the exact pathologic diagnosis remains still in doubt, an exploratory laminectomy should be performed (caries being absolutely excluded). If the growth has been allowed to remain beyond this stage, paraplegia develops and a complete compression of the cord or a transverse myelitis results. Probably no one will then doubt the existence of a tumor, but irreparable damage has been done; spinal-cord tissue does not regenerate. Extramedullary tumors are frequently benign, and restitution may be expected provided the neoplasm is removed at the opportune time. Dr. Abrahamson has now under observation three such cases, two at the Neurological Hospital, Blackwell's Island, that were operated on by Dr. Charles Elsberg, and another at the Montefiore Home operated on by Dr. Kiliani over seven years ago at the German Hospital. The restitution in these cases has been almost complete.

Circumscribed serous meningitis also produces symptoms very similar to those of extramedullary tumors, and a differential diagnosis is frequently impossible. The root symptoms and the pains so characteristic of tumors, however, are not pronounced in some instances of circumscribed serous meningitis. An early laminectomy is required in either case, and therefore an exact pathologic differentiation is not of practical importance.

The diagnosis of intramedullary tumors is at times easy and at other times exceedingly difficult. In this condition we do not have the incipient symptoms occurring alone which are seen in the extramedullary type, but they are associated from the very beginning with cord symptoms, such as tract involvement.

A number of conditions may be mistaken for intramedullary growths, such as syphilis, gliosis, syringomyelia, progressive muscular atrophy, multiple sclerosis and tuberculosis of the cord. There is, however, one characteristic sign that differentiates a tumor from all these enumerated conditions, namely, root symptoms, which, from the onset, accompany the cord symptoms.

Syphilis has previously been discussed. Gliosis spinalis and intramedullary tumors cause very similar symptoms and an exact differentiation between the two is in many instances impossible. It is well to remember, however, that the incongruity of sensory and motor symptoms, is characteristic of gliosis and syringomyelia. In other words, the sensory disturbances are wide-spread and do not correspond to the amount of motor disturbances. Pathologically, gliosis, syringomyelia and gliosarcoma are very closely related and one may be transformed into the other.

Again, besides the characteristic and often wide-spread sensory symptoms peculiar to syringomyelia, there are trophic changes in the skin, muscles and bones early in the disease, while in tumors such symptoms are of late appearance. Progressive muscular atrophy has no sensory disturbances. In multiple sclerosis, sensory disturbances are rarely very pronounced. The symptoms are wide-spread, rarely focal. There is intention tremor, optic atrophy and characteristic speech. Tuberculosis of the cord, as shown by Oppenheim is usually confined to the gray matter of the cord. Tuberculosis of another organ is usually found present.

The outlook for a good result following an operation is not as bright as in the extramedullary variety. It was recently shown, however, especially by Dr. Elsberg that even in this condition the removal of the tumors can be successfully accomplished by a process of extrusion, and if of a benign and circumscribed character, fair restitution can be obtained.

CONCLUSIONS

1. Comparing the two cases presented, it is evident that considering the nature and the situation of the growth in Case 1, had it been early diagnosed and removed before paraplegia set in, the result of the operation would have been brilliant. In Case 2, the tumor being infiltrating and involving the pia, an operation most likely would not have been very effective. Bearing in mind, however, that even central neoplasms may be benign or at their early stage circumscribed and not infiltrating, a surgical technic as developed by Dr. Elsberg ought frequently to give us satisfactory results.
2. An early diagnosis is of paramount importance.
3. A careful study and charting of the sensory disturbance will always establish the level.
4. Wherever a persistent level is established and is associated with some other suggestive symptoms an exploratory operation should be performed at the earliest possible moment, even if the exact pathologic process be still undetermined.
5. With present surgical skill, less damage will be done by an exploration than by allowing the cord to be injured beyond repair.

Prevention.—The death of a single child by violent means causes a shudder to pass through a million minds, but the slaughter of a million innocents by preventable disease is complacently called the act of Providence.

THE DORSAL POSITION DURING THE PUERPERIUM AS A CAUSE OF RETROVERSIO UTERI

W. C. GAYLER, M.D.
Instructor in Gynecology, St. Louis University School of Medicine
ST. LOUIS

During the year ending Aug. 1, 1913, there were 105 papers published on the subject of uterine displacements throughout the world.[1] Of all these papers, only one-half of one paper was devoted to the etiology of these conditions (other than obstetric injuries). These papers represent a tremendous amount of work. Practically every paper mentioned the injuries incident to delivery as causative factors, but other causes were ignored. The subject of posterior displacements without obstetric injuries to the genitalia was scarcely mentioned. The literature classifies the causes of the above-mentioned condition about as follows:

1. Congenital lack of ligamentary tone throughout the body.
2. Pelvic inflammatory trouble, followed by adhesions.
3. Extreme distention of bladder and rectum, pushing cervix forward and fundus backward.

A very few authors (gynecologists, not obstetricians) are now adding a fourth cause, "the dorsal position during the puerperium."

Both permanent and movable displacements receive their chief impetus in the days immediately following delivery. The involution of the uterus, ligaments, vagina, vulva and perineum is a physiologic act, and should therefore leave no defect or malposition behind it. The uterus after delivery is not only large and heavy, but is more freely movable than at any other time during the life of the woman. Bumm[2] says:

> The movability of the uterus and vagina during the puerperium is tremendous. It can happen that the fundus is pushed up to, and under the border of the ribs, when the bladder is greatly distended.

While delivering a woman who had previously had the round ligaments shortened by the Gilliam operation, it occurred to me that the dorsal position would be contraindicated during the puerperium. We can safely assume that this uterus was held in the anterior position by the round ligaments, and by them alone. She had had a complete retroversion previous to her operation, and the round ligaments *only* had been shortened. We can, therefore, dismiss the possibility of help from the broad or sacro-uterine ligaments. It seemed to me that these round ligaments *might* stand the strain of the dorsal position, but why make the experiment?

We now come to the question, Are we ever justified in putting the recently delivered woman in the dorsal position? The uterus is then larger and heavier than at any time during the life of the woman, excepting before delivery, when a posterior position is impossible. The ligaments have not undergone involution, and cannot support the uterus. The normal bladder irritability is usually lacking for several days, often causing unsuspected bladder distention. An overdistended bladder, more than anything else, will tend to push a uterus out of position. In short, it would seem that the dorsal position during the puerperium is the ideal condition for the production of retroversio uteri. We have:

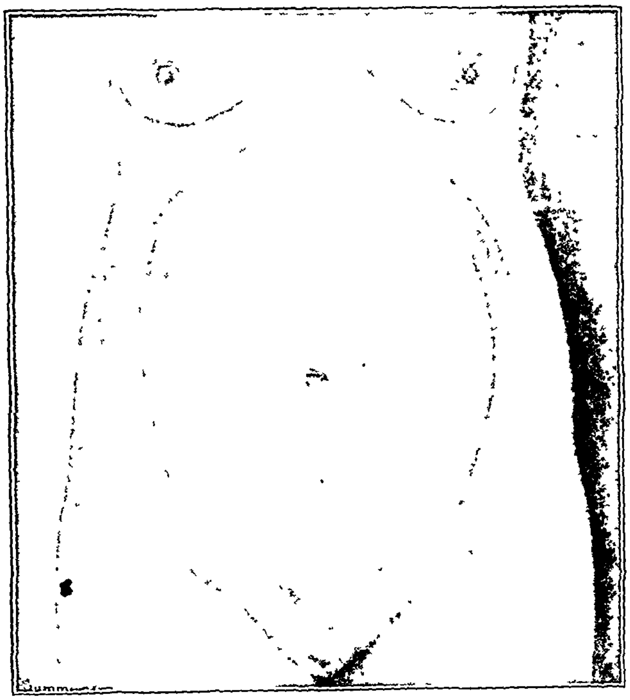
---

[1] Index Medicus

[2] "Die Beweglichkeit der Gebarmutter und Scheide in den ersten Wochenbettstagen, ist eine grosse. Es kann geschehen dass man den Fundus uteri, bei starker Blasenfüllung am, und selbst unte dem rechten Rippenrande findet."

1. Temporarily weakened ligaments.
2. Lack of any but ligamentary support.
3. Exceedingly heavy and freely movable uterus.

Of the last seventy-four patients entered in the gynecologic clinic of the St. Louis University, eleven had uterine malposition. Only four of these eleven were uncomplicated by perineal and other injuries. One of the four was a virgin with splanchnoptosis, thus leaving three women who had borne children, and who had retroversio uteri uncomplicated. These three patients all declared that the symptoms started shortly after delivery. All three spent the ten days following delivery flat on the back, without being permitted, even for a short time, to change position. Inasmuch as the midwives of St. Louis rarely permit their patients any but the dorsal position after delivery, there is nothing surprising about the way these women were treated. Surely these patients owe their troubles to stupid insistence on the dorsal position during the puerperium.



Is it reasonable to expect these round ligaments to hold this uterus in anteversion, after delivery, with the woman in the dorsal position?

Practically all the text-books on obstetrics used at present ignore the question of the position during the puerperium. Some of the books on gynecology mention the subject, but the dorsal position during the puerperium is not universally recognized as a cause of retroversio. Many authors, in private letters that I have had, admit the importance of the subject, and some are going to mention it in their next editions.

The illustration gives an idea of the tremendous changes that take place in the round ligaments during pregnancy. Is it reasonable to expect these round ligaments to hold this uterus in anteversion after delivery, with the woman in the dorsal position?

If we assert that a return to the four-footed manner of life would remove posterior uterine displacements, we state an interesting fact that cannot possibly be demonstrated. If we ask, however, that woman remain off her back during her puerperium, thus taking a lesson of the lower animals, we ask something that is possible of fulfilment. To spend most of her time on her right and left sides, occasionally to be flat on her abdomen, or to assume a position slightly on her side but almost on her abdomen, would seem a logical procedure for at least eight days. Bumm says that the uterus loses half its weight in the first eight days following delivery. The involution of the round ligaments is probably well advanced by that time.

I certainly think that the dorsal position should be prohibited during the puerperium, unless there seems to be an interference with the flow of the lochial discharge while the woman is in other positions.

SEVERE CUTANEOUS ERUPTION FOLLOWING NEOSALVARSAN

REPORT OF TWO CASES *

B. A. THOMAS, M.D.
Professor of Genito-Urinary Surgery in the Philadelphia Polyclinic Hospital and College for Graduates in Medicine

AND

S. W. MOORHEAD, M.D.
Instructor in Genito-Urinary Surgery in the Philadelphia Polyclinic Hospital and College for Graduates in Medicine

PHILADELPHIA

The two cases herewith reported presented unusual and severe complications following the administration of neosalvarsan. In both cases the skin alone was affected, other portions of the body apparently escaping all deleterious effects of the drug. Each patient received three doses of neosalvarsan, at intervals of about a week. The first case was in the primary stage of the disease, the second in the tertiary; in neither were any skin lesions present prior to the injections. The cutaneous eruption appeared in both after the third injection (twelve days in one case and seven in the other). The first patient had had a small amount of mercury, and it was at first thought that this was responsible for the condition; the second patient received no mercurial medication in connection with the arsenical injections.

When about a week old the eruptions on the two patients were strikingly similar, both being symmetrical and diffuse, with moderate infiltration of the skin. In both cases the surface was slightly roughened. The subsequent courses, however, were rather different. In Case 1 the reaction was much more severe, and there was greater prostration, though the course of the disease was shorter; in its terminal stages the eruption developed into a well-marked dermatitis exfoliativa. The second case retained the characteristics of an eczema throughout its course.

In forming an opinion as to the etiology of the eruption, the possibility of an analogy to the Jarisch-Herxheimer reaction is to be considered, as in some cases the energetic administration of mercury and arsenic has resulted in a severe dermatitis of syphilitic causation. The fact that Case 1 has had a continuously negative Wassermann reaction for more than ten months and is clinically free from all signs of the disease would seem to militate against this view.

---

* Read before the Philadelphia Genito-Urinary Society, Nov. 24, 1913.

Case 1.—Man, aged 22, Jewish, with a chancre of three weeks' duration (the *Spirochaeta pallida* found by dark-ground illumination), received a dose of 0.75 gm. neosalvarsan, Nov. 20, 1912. There was a trace of albumin in the urine prior to the injection. As the albuminuria did not become more marked and there was no subjective reaction, doses of 0.9 gm. were given on November 27 and December 2. In addition he was given mercury protiodid, 1 grain a day, beginning November 29. The gums quickly became tender, so that the mercury could not be increased; in fact it was taken very irregularly till December 24, when it was stopped altogether. Inunctions were given for two days.

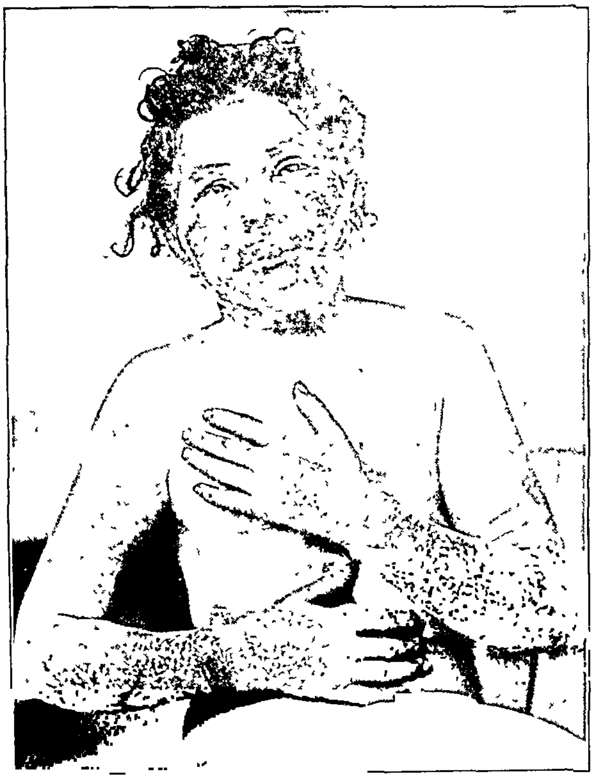

Fig. 1.—Height of the eruption in Case 2.

December 14 the patient noticed that his body was red. When he reported two days later his trunk and upper extremities were covered with a diffuse eruption of a dark copper-color. The surface was slightly roughened; itching was intense. The eruption gradually grew more severe and more extensive, and assumed the characteristics of a severe caloric dermatitis. The skin of the chest, abdomen, upper extremities, face and neck were the regions most affected at the beginning of the attack; the back was but slightly involved. Inflammation of the skin of the genitalia and lower extremities appeared later and was of great severity. The patient was confined to the house from December 24 till February 12, during the greater part of which time he was in bed. His face became so swollen that one eye was nearly closed. There was much secretion of a serous character, which exuded from all portions of the body, necessitating changes of the bedclothing several times a day. Moderate elevation of temperature was present during the greater part of the time; 101.8 F. was the highest recorded. Prostration was extreme, and there was a marked muscular tremor. Strange to say, the character of the urine steadily improved, and when the disease was at its height no albumin was present; casts were never found. Finally a well-marked dermatitis exfoliativa developed, the greater part of the body being scarlet, with patches here and there of desquamating epithelium. At this time there was also a marked edema, especially of the upper extremities. Recovery was accompanied by universal desquamation, loss (temporary) of the greater part of the hair, and ridging of the nails.

At present the patient is apparently in perfect health. He has gained weight and shows no evidence of the dermatitis or his spirochetal infection. The Wassermann has been continuously negative, the last test having been made on Oct. 20, 1913.

Case 2.—Annie B., aged 35, Jewish, referred by Dr. Henry Golden, was admitted to the Polyclinic Hospital June 11, 1913, complaining of excruciating migraine. She had had four miscarriages, the last thirteen years ago, and some of her four children showed stigmata of congenital lues. She gave no history of primary or secondary lesions; her husband had a chancre twenty years ago. She had been having severe headaches for the last eighteen months at intervals of three or four weeks. At times the pain was almost intolerable and prompted thoughts of suicide. The duration of the attacks was about two weeks. The results of two Wassermann reactions had been strongly positive. The urine contained a few hyaline casts on admission.

The patient was given intravenous injections of 0.9 gm. neosalvarsan on June 11, June 19 and July 3. The first injection was followed by a transient trace of albumin in the urine, and a temperature of 99 F. After the second injection she complained of vertigo, nervousness and epigastric distress. Temperature rose to 102, and pulse to 120, both becoming normal in twenty-four hours. She also had a macular rash on her arms and chest, lasting forty-eight hours. Neurologic examination showed no lesions of the nervous system other than the chief complaint.

She was readmitted to the hospital on July 22, complaining of burning and itching of the skin. She stated that one week after the third injection of neosalvarsan her face began to swell and an eruption appeared. One week later the extensor surfaces of the forearms exhibited an eruption beginning as an erythema, changing to diffuse millimeter-sized papules, and finally passing into a pustular stage. On the day of readmission the patient's skin was red and hot, and the entire body surface was covered with a diffuse maculopapular eruption, excepting that on the extensor surfaces of

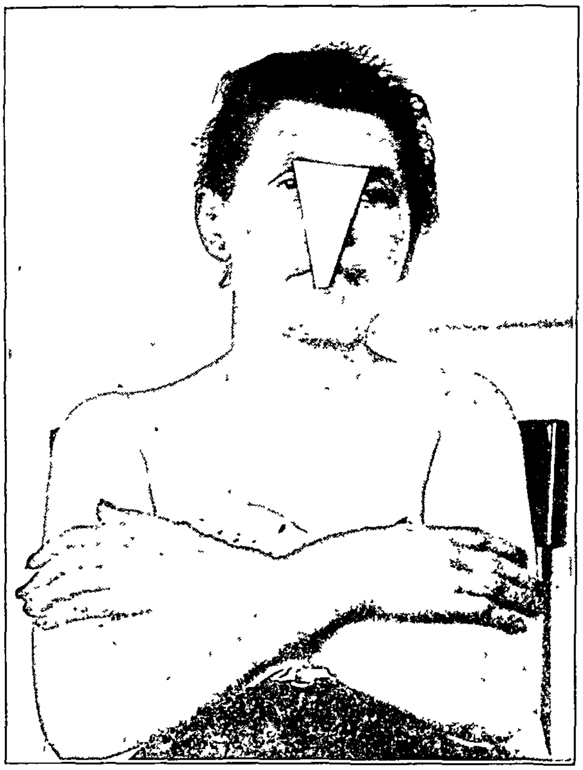

Fig. 2.—Patient after recovery.

the forearms pustules were superadded. The loose tissue of the face, neck, ears, lips, hands and legs was very edematous, imparting the sensation of an infiltration. No moisture of the skin was present. Burning and itching were intense. Temperature, pulse and respiration were essentially normal at the beginning of the attack and for a week following its advent. A second neurologic examination was negative save for a slight peripheral neuritis. Urine contained a trace of albumin, but no casts. Blood was normal; blood-pressure, systolic 128, diastolic, 78.

The condition became rapidly worse, being most marked on the face, forearms, scalp, arms, chest, legs, back and abdomen, in the order named, and had the appearance of an acute erythematous papulosquamous eczema. There was much oozing of serum and subsequent crusting of the surfaces most involved. Figure 1 represents the condition at the height of the attack. At no time was the patient greatly prostrated, but spent most of her time sitting up in bed. The temperature was markedly intermittent, and ranged from 96 to 102 F. (Fig. 3). The urine showed no abnormalities other than those *already noted.*

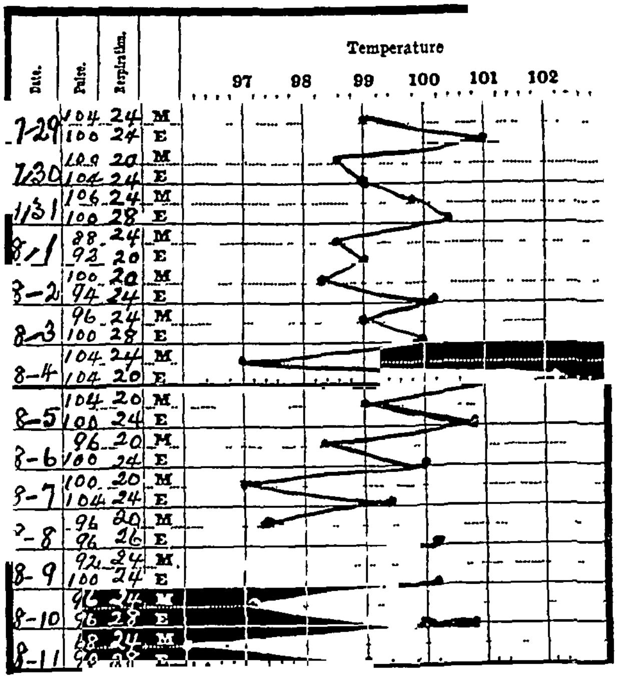

Fig. 3.—Temperature chart in Case 2.

The skin was entirely normal with the exception of a patch of eczema rubrum on one leg on November 22, when the second picture was taken (Fig. 2). There was marked thickening of the nails, however. The patient has had no headaches since receiving the neosalvarsan. The Wassermann reaction is still strongly positive.

116 South Nineteenth Street.—1523 Pine Street.

Some Hygienic Fallacies.—The new hygiene has given us an entirely different conception of many of the factors that enter into health and disease. It has exploded many a world-old fallacy. We know, for example, that there is practically no more danger from sewer-gas than the farmer subjects himself to on his manure-pile. The old bugaboo of sewer-gas dies hard. People have always clung, and still naturally cling, to the notion that anything that smells bad must be detrimental to health. Science has demonstrated that our sense of smell is a poor sanitary guide. It is certainly absurd to accuse the odors from plumbing of being the source of diphtheria, typhoid fever, scarlet fever, sore throat, or any other infection.—M. J. Rosenau in *Vermont Med. Month.*

FLUOROSCOPIC BRONCHOSCOPY

E. FLETCHER INGALS, M.D.
AND
STANTON A. FRIEDBERG, M.D.
CHICAGO

REPORT OF CASE BY DR. INGALS

About three years ago Mr. X., aged 42, drew into the air-passages a band of gold that had been fitted around the last molar tooth as a part of a crown. This measured 0.5 mm. in thickness, from 4 to 7 mm. in height at different places, and from 1 to 1.2 cm. in diameter. It was elongated to 1.4 cm. by pulling through the stricture mentioned below. At the time of the accident this was supposed to have passed down the esophagus. It lodged in the first branch of the right bronchus going to the upper lobe of the right lung. The patient had been suffering from a severe bronchitis for several years. After the accident he had four bronchiectatic abscesses in the upper lobe of the right lung, the last about four weeks before coming to me. The true nature of the trouble was not discovered until he came under the observation of Drs. E. L. Timmons and G. B. Webb of Colorado Springs, who made the diagnosis and sent him to me.

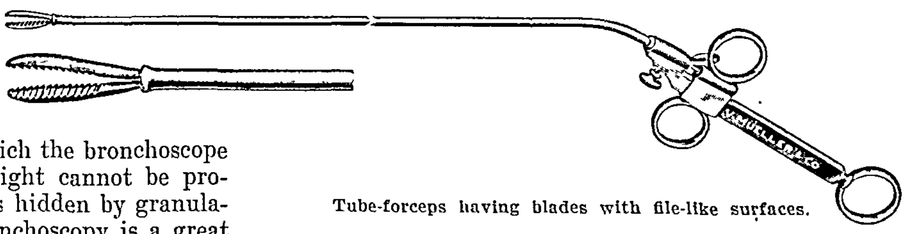
At the Presbyterian Hospital, Nov. 28, 1913, assisted by Dr. Stanton A. Friedberg, I did bronchoscopy under local anesthesia. We found a large cicatrix where we should have found the opening of the bronchus, which had been so constricted that it was impossible to penetrate the stricture with the bronchoscope, or with any rays of light; indeed, we were unable to locate surely the fistula through which the mucopus slowly escaped; but we could see a small depression that appeared to be its mouth. Careful probing did not enable us to find the opening or locate the foreign body, and after a long search we found the task hopeless. I placed the patient in a croup tent for three or four days, until the reaction caused by the operation had subsided. December 3, under local anesthesia, I repeated the bronchoscopy aided by the fluoroscope. Drs. S. A. Friedberg and J. E. Rhodes assisted me and Messrs. Earl Ball and G. W. Wallerich, for Dr. Potter, managed the Roentgen apparatus. Having passed the bronchoscope down to the scar tissue, with the aid of the fluoroscope, I directed it accurately toward the foreign body, which was found to be about 3 cm. beyond the end of the tube. A strong tube-forceps was then introduced. By firm pressure the bronchoscope was carried to within about 1.5 cm. of the shadow of the foreign body, and the forceps was then carefully pushed through the stricture, which appeared to be about 3 mm. in diameter. When the shadow indicated that the forceps had reached the foreign body, the instrument was moved laterally back and forth to assure me that it was in the same opening with the foreign body, and when I had satisfied myself on this point, I opened the blades and pushed the forceps onward about a centimeter and closed them on the gold band, which was grasped with one blade inside. Traction at once brought the shadow of the gold band into apposition with that of the end of the tube, and quickly convinced me that I had a firm grip on the foreign body. Continued traction for two or three minutes with what I estimate about 6 pounds of force gradually drew the band through the stricture until it suddenly snapped out at the proximal end, and I thought the forceps had slipped off; but renewed traction showed me that the foreign body was against the end of the tube and I then drew out the two together. The band had been considerably flattened and elongated by being pulled through the narrow stricture.

The patient had suffered practically no pain during the operation notwithstanding the strong traction that had been necessary. He was again placed in a croup tent for forty-eight hours, but there was little or no reaction, and on the fifth day after the operation he was ready to leave the hospital. A week after the operation he had gained 10 pounds.

The forceps used in this case (shown in the accompanying illustration), was a simple tube-forceps, which was attached to a Krause handle; and it is far and away the best instrument for removing metallic or hard bodies that I have ever seen. It is strong and of small diameter, so that it will pass through any tube that can be used in bronchoscopy. Its chief characteristic is in the grasping surface of the blades and the strength of the spring by which the blades are opened as they are protruded through the tube. The surface of these blades is cut like a file with the cutting edge toward the handle, so that the harder the pull the firmer they grasp the body.

I had this forceps made for a similar fluoroscopic bronchoscopy. In that case a child had a shingle-nail in one of the tertiary divisions of the left trunk-bronchus with the head upward. The nail was in such a small tube and its head so hidden by granulation tissue that it was impossible to see it. Aided by the fluoroscope, I was enabled to grasp the head of the nail, but the various forceps employed repeatedly slipped off and I was obliged to desist. I then had this forceps made and secured the nail at the next operation. This forceps has not slipped in any case in which I have used it.

In the case of the child, I learned an important thing for fluoroscopic bronchoscopy. When the forceps has been passed down so that its shadow reaches the shadow of the foreign body, the end of the instrument should be moved back and forth laterally to determine whether or not it is in the same bronchus or cavity as the foreign body. If it is in a different tube the shadow of the forceps will pass away from that of the foreign body, but if in the same bronchus, the shadow of the foreign body will move with that of the instrument.



Tube-forceps having blades with file-like surfaces.

When a metallic body has passed into a fine bronchus, into which the bronchoscope cannot enter; or into which the light cannot be projected; or when the foreign body is hidden by granulation or scar tissue, fluoroscopic bronchoscopy is a great aid in its removal.

In using this method it is most important for the operator to assure himself that his forceps is in the same tube or cavity as the foreign body and that he is not grasping lung-tissue. A strong, slender, never-slip forceps is essential to success.

Just a week after this operation I assisted Dr. Friedberg in a similar operation, the history of which he adds to this report.

REPORT OF CASE BY DR. FRIEDBERG

A boy, aged 9, stated that two years ago last summer (August, 1911), he was lying under a tree with a brass bolt in his mouth which he aspirated. A violent coughing-spell immediately ensued. He told no one of the mishap until last June. One week after the accident he became ill with what his physicians called congestion of the lungs. This spell lasted for three weeks. He recovered from this attack but was not well or strong. He had a hacking cough until last winter when the cough became loose and he raised a great deal of a foul-smelling material. From time to time the patient had headache and high temperature. He failed to develop as a boy of his age would normally. In June, 1913, he was taken to Port Huron, Mich., to consult Dr. B. E. Brush. A diagnosis of abscess of the lung was made and posterior drainage was established. A roentgenogram which was taken before the operation showed the bolt in the lower part of the left lung and search was made for it at the time of the operation. Following the operation for drainage, the boy gained 15 pounds in weight. The wound closed at the end of about six weeks. During the fall the symptoms returned. He coughed a great deal and raised large amounts of pus. He was referred to Dr. Arthur Dean Bevan at the Presbyterian Hospital, who kindly asked me to assume charge of him. His temperature on admission was 100.4 F., pulse 120, respiration 28.

Examination showed a frail, undernourished boy. The respiratory movements of the left side of the chest were markedly diminished. There was a large scar with retraction over the lower part of the left chest from the former operation. Dulness was present all over the left side on percussion, being less marked over the upper lobe. The respiratory sounds were feeble over the upper lobe, with some moist râles present. Over the lower lobe the signs were those of a cavity with loud bubbling râles. No tubercle bacilli were found.

Bronchoscopy was done under local anesthesia. A continuous flow of very foul pus appeared as soon as the tube was introduced. It was impossible to see anything or do anything on account of this condition. After suction and swabbing had been carried on for almost half an hour the failure of the lighting apparatus compelled me to stop. Two days afterward the second trial was made by fluoroscopic bronchoscopy. The larynx was cocainized and a tube introduced. There was still a large amount of pus present, but there was less difficulty in clearing the bronchus. The tube was carried downward to the bronchus from which the pus appeared to come when the lighting apparatus, which had just come from the repair-shop, failed again. The fluoroscopic screen was then used. The forceps described by Dr. Ingals was introduced through the tube and I could feel it slip through a narrow opening into a cavity. With the screen, which was managed by Dr. Ingals, the movement of the tube and forceps was controlled, and I am greatly indebted to him for his aid. As shown by the shadow, the bolt was at first grasped about the middle, but as it would have been impossible to extract it in this position it was loosed and finally a hold was secured at its head, when it was brought out with the tube. Much pus and some blood immediately followed. The boy, however, was in good condition and complained only of some pain and soreness in the neck following the operation.

The diameter of the head of the bolt was 8 mm., and the entire length was a little over 17 mm. The temperature went to normal the next day, December 11. On December 12 it went as high as 100.4 F. December 13 and 14 it reached 102 F. On December 15 it rose to 104.2 F. No evidence of pneumonia could be found. The boy was still coughing and raising a large amount of pus, so the expedient was adopted of raising the foot of the bed and keeping the head low for a certain number of hours at intervals each day. This seemed to assist the drainage. On December 16 the temperature dropped below 100 F., at which point it remained for the next four days when, on the insistence of the father, he was allowed to return home. The respirations were from 18 to 20, the pulse 88 on his discharge.

Inasmuch as the changes produced in the lung as a result of the long-continued presence of the bolt were so extensive, it is somewhat doubtful what the ultimate outcome will be. Naturally, the conditions for recovery are better now than before the operation. If progress is not satisfactory, I believe that it will be both advisable and necessary to reestablish the posterior drainage.

104 South Michigan Avenue.

TRAUMATIC EPILEPSY

REPORT OF A CASE OF FIVE YEARS' DURATION CURED BY SURGICAL TREATMENT

WILLIAM M. LESZYNSKY, M.D.
Neurologist to the Lebanon and Harlem Hospitals
NEW YORK

Many years of experience and observation have shown that surgical operation on the skull or brain for the cure of epilepsy has well-defined limitations. The indications for operation are: (1) epilepsy following cranial traumatism; (2) jacksonian epilepsy, and (3) grand mal attacks in which there are distinct clinical evidence of a focal lesion.

The earlier the operation is performed after the cranial traumatism the more favorable the prognosis. As a rule, when the epilepsy has continued for a number of years, the epileptic habit, as it were, has become established, and hence operation, such as the removal of depressed bone, separation of adhesions, or excision of a portion of a cortical center ofter proves futile.

In the case herewith reported the cranial injury occurred during childhood. The epilepsy developed fifteen years later, and continued for five years.

Charles L., a bookkeeper, aged 26, first consulted me May 18, 1910. At the age of 6 he fell from a height and received a compound fracture of the skull over the vault on the right side. He was removed to a hospital and prompt surgical treatment instituted. Several weeks later he was discharged without any apparent residual symptoms of the injury. He soon returned to school and in the course of years his physical and mental condition developed normally. He remained in perfect health until the age of 21 (fifteen years after the injury), when he had an attack of clonic spasm affecting the muscles of the left hand and forearm, which was almost immediately followed by loss of consciousness and a general epileptic convulsion in which he bit his tongue. These attacks have recurred about once a month during the past five years, and have not varied in character or intensity, often taking place during sleep. Two days before he visited me he had four severe attacks during one night. He has never suffered from headache, save immediately after the epileptic paroxysm. There is no history of venereal disease, alcoholism or masturbation. He does not use tobacco. The gastro-intestinal tract functionates normally, the general health is good, and the patient follows his occupation regularly unless temporarily incapacitated by an attack.

Examination shows a well-developed young man in good physical and mental condition. Over the right temporoparietal region there is an irregularly shaped deep depression, (the bone having been surgically removed at the time of the cranial injury), 1½ inches in diameter about 3½ inches above the mastoid process, and 2 inches from the median line. The pupils and eye-grounds are normal. Further physical examination reveals nothing otherwise abnormal.

It being quite evident that the epileptic attacks were due to focal irritation from a cortical lesion resulting from the original traumatism, an *early operation was advised.*

The patient entered the Lebanon Hospital five days later and the operation was performed May 23, 1910, by Dr. Henry Roth, one of the attending surgeons, to whom I am indebted for the following notes:

"There was a scar from a curved incision over the right temporoparietal region. Within this there was another crucial scar, which was hard, depressed, adherent and pulsating. The central area showed absence of bone, and was about 1½ inches in diameter. A semicircular incision was made surrounding the outer curved scar in the right temporoparietal region. The pericranium was raised from the skull by dissecting inward toward the scar. The edge of the bone defect was removed, exposing the normal dura. The dura was then incised and carefully dissected off the brain-tissue, to which it was firmly adherent at the cicatricial area. The raised flap consisted of scalp and dura directly over the precentral convolution including all of the scars. After all bleeding was checked, the exposed brain-tissue was covered with Cargile membrane. The flap was replaced and sutured with silk, a small rubber-tissue drain being left in the lower angle of the wound. The drain was removed on the third day, and the sutures on the seventh day following the operation. He was discharged from the hospital June 11, 1910."

The patient was under my observation and reported to me regularly during the following year. He has never had any form of epileptic attack since the date of operation, a period of three years and seven months having elapsed. His general health has been good and he has attended daily his occupation as a bookkeeper. The treatment subsequent to the operation has been simply hygienic. He has never received any form of bromid or other sedative drugs.

ANASTOMOSIS OF THE FACIAL AND HYPOGLOSSAL NERVES FOR FACIAL PARALYSIS *

Cullen F. Welty, M.D., San Francisco
Surgeon Chief of Otology, San Francisco Polyclinic; Otologic, Rhinologic and Laryngologic Surgeon, St. Mary's Hospital, and City and County Hospital; Consulting Otologic, Rhinologic and Laryngologic Surgeon, German Hospital

Patient.—J. T., a man, aged 23, was shot in the right ear in September, 1909. Patient was in a local hospital for one month after he was hurt because of intense vertigo, nausea and vomiting. Facial paralysis was observed on the day following the accident.

Examination (September, 1910).—Face: complete paralysis. On the injured side the eye cannot be closed; cheek muscles are flabby, all lines obliterated, and forehead smooth (Fig. 1); mouth is drawn to the opposite side. The condition is accentuated when patient smiles (Fig. 2). No response to either faradic or galvanic current. No nystagmus or vertigo. Ear: Foul discharge, the meatus considerably contracted from the gunshot wound. The scar is about a quarter of an inch within the meatus, posterior and above. Because of the contracted meatus and the destruction, the parts cannot be recognized. From the location of the scar it is reasonable to believe that the facial nerve was not cut, but pressed on by a fracture. By tuning-fork: Weber to the good ear; Rinne

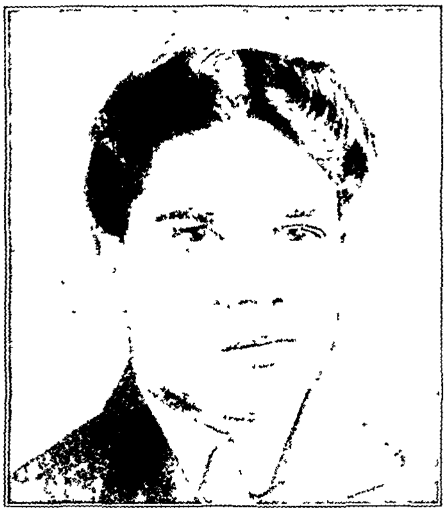

Fig. 1.—Facial paralysis from gunshot wound in right ear. Face in repose. Note obliteration of lines on affected side.

---

* Read before the Surgical Section of the San Francisco County Medical Society, Oct. 21, 1913.

negative, heard in the good ear; injured ear completely deaf as proved by Neumann's noise apparatus; caloric reaction negative. By Roentgen ray: Bullet located in the petrous portion of the temporal bone.

With a bullet located within the petrous portion of the temporal bone, no hearing on the injured side, caloric reaction negative, the proof is almost positive that the facial nerve is so destroyed that it can never regain function.

Operations.—The ordinary radical mastoid operation was performed to remove the bullet and the chronic suppurative process; the entire posterior wall was found to be destroyed by the gunshot; tegmen tympani and antri intact; no other fracture apparent macroscopically; bullet imbedded to its depth in the region of the promontory of the petrous portion of the temporal bone. No trace of the facial nerve was found at operation, which was completed by the Neumann plastic; wound closed posteriorly; cavity entirely dermatized in six weeks. One month after complete epidermization the anastomosis with the spinal accessory was attempted. The spinal accessory was anomalous in this patient and the hypoglossal nerve was substituted. The facial nerve was severed at its exit from the stylomastoid foramen, the hypoglossal nerve was severed low down and an end-to-end anastomosis was made. Very fine thread was passed through the sheath of the severed ends of the nerves; the suture was repeated on the opposite side. An additional suture of catgut was inserted through the center of the nerves in their longitudinal axis. The sutured nerves were surrounded by Cargile membrane, which did not remain in position and was removed. The nerves were replaced under the stylohyoid muscle, which had been severed for better access to the nerve. The muscle was sutured and the wound closed in the usual way. Healing took place in a very short time.

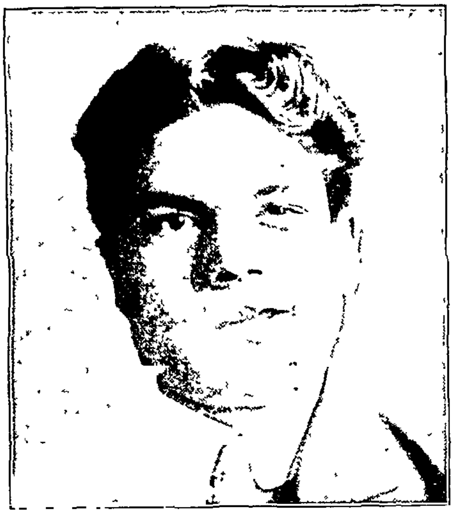

Fig. 2.—Patient shown in Figure 1, smiling. Condition best seen by alternately covering half of face.

Postoperative History.—About one month after the anastomosis, galvanic electricity was applied on alternate days for a period of two months. Faradic electricity was used on alternate days for a further period of two months. At no time did I notice any contraction of the muscles of the side of the face operated on. For the following four months, galvanic and faradic electricity were used alternately. During the latter part of the treatment I thought I noticed some fibrillar contractions about the mouth from the faradic current. This was nine months from the time the anastomosis was made. Regular office treatment was discontinued; patient was directed to purchase a battery, use it on alternate days and report to me once a month.

I did not see the patient again for about two years. A few months ago, he returned to me with the following history: At the end of one year following the anastomosis operation, he began to notice that he could move his face and during the next year he had electricity applied every other day. Since then the galvanic current has been applied at longer intervals.

At present, three years after the anastomosis, the injured side of the face moves when the patient talks; the muscles have recovered their tonicity. He can close his eye, wrinkle his face, lift the eyebrow. A smooth spot remains on the forehead on the injured side. The cerebral center of the anastomosed hypoglossal nerve has anatomically changed and now controls the muscles of his face.

Dr. Walter F. Schaller furnished me the accompanying tests under date of Nov. 21, 1913.

ELECTRICAL TEST IN CASE OF FACIAL PARALYSIS THREE YEARS AFTER ANASTOMOSIS OF HYPOGLOSSAL AND FACIAL NERVES*

Nerve or Muscle	Far	Right Galvanic m.a.	Far	Left Galvanic m.a.
N. Facialis (root)	250	4	200	2
Facialis upper branch..	225	3	150	2
Facialis lower branch..	200	4	140	2
M. Frontalis	225	4	125	3
Orbicularis palpebrarum	140	4	75	2
Orbicularis oris	175	6	75	4
Levator menti.........	175	6	75	2

* Reaction throughout, Kcc>Acc quick. No reaction of degeneration; nerves and muscles of affected side show hypoexcitability to both forms of current. Electrodes: Indifferent cm.², 16; examining, cm.², 0 75 Gaiffe faradic coil, bobine medium. Power from three dry batteries.

Figure 3 shows the atrophy that follows the cutting of the hypoglossal nerve. A slight impediment of speech exists, which is of little moment to this patient, but for one in a different social position it would amount to a real handicap. Just recently I saw a friend who has had Bell's paralysis for twenty-five years or more. At present this man occupies a very important position in which a considerable amount of talking is necessary. Had the hypoglossal nerve been severed it would have caused a real handicap to this patient in the matter of speech. Had the spinal accessory been used with success, however, I am confident it would have prevented the drooping and turning outward of the lower lid. The tonicity of the muscles would have been such that in repose, at least, the facial paralysis would not have been obvious.

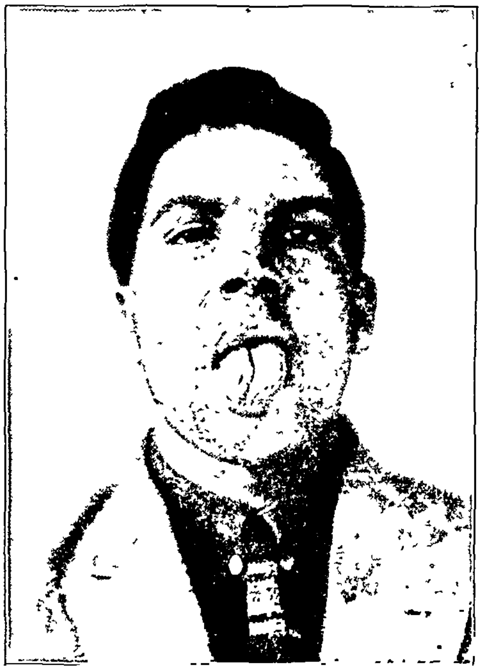

Fig. 3.—Patient shown in Figure 1 three years after anastomosis operation. Atrophy of tongue as result of severing hypoglossal nerve.

For this reason alone, I believe the spinal accessory should be the nerve of selection rather than the hypoglossal.

Shreve Building.

COMMINUTED GUNSHOT FRACTURE OF THE FEMUR, WITH FIXATION BY BONE-PLATE AND WIRES

F. B. Lund, M.D., Boston

On June 22, 1913, the patient was shot in the right thigh by a 0.32-caliber revolver in the hands of a policeman, the bullet shattering the femur. He had been put to bed with extension, but the position was poor; the leg was considerably bowed outward. He was very uncomfortable, with a *2-inch shortening, and had a high temperature.* Roentgenograms taken by Dr. Ellsworth showed a fracture of the upper third of the femur (Fig. 1), with a piece about 5 inches long split out of the bone, and marked anterior projection of the upper fragment. I saw the patient in consultation with Dr. Walter Sargent of Quincy.

At the Quincy Hospital, July 2, with the assistance of Dr. N. S. Hunting and Dr. Sargent, I made an external incision 12 inches long, exposed the bone, and under strong extension brought the ends together with some difficulty and forced the fragment into place with Bartlett's clamp, so that the contour of the bone was very good indeed. Then an 8-screw Lane plate of the largest size was applied. I could insert only three screws in the upper fragment, but four were placed in the lower. The detached fragment, which lay at some little distance from its proper position, was bound by two silver wires passed around bone, plate and all, thus restoring the fragments practically to their normal position, in which they have since remained. A plaster-of-Paris spica was put on.

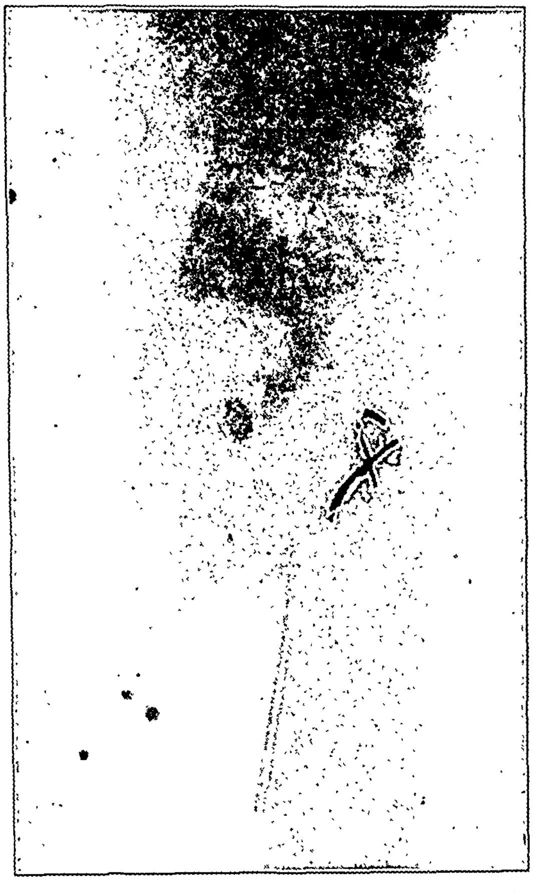

Fig. 1.—Position of the two principal fragments before operation; the detached piece is not shown.

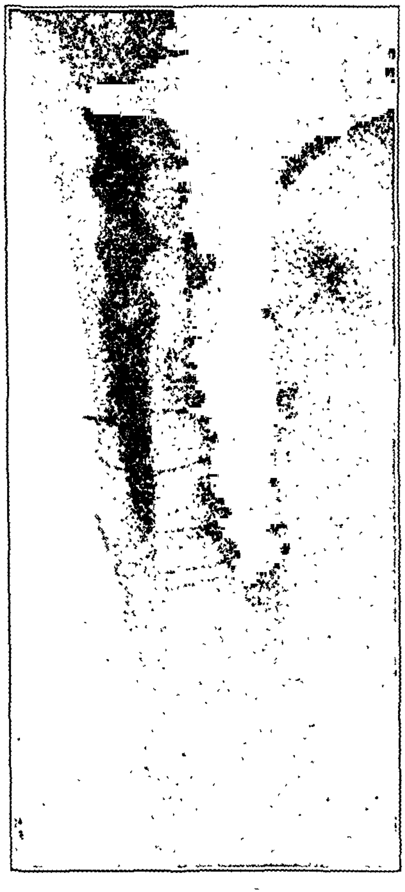

Fig. 2.—Postoperative roentgenogram.

The wound healed by first intention and the bone remained in first-class position. The patient came to my office for observation, October 25. I found the leg perfectly straight, and he was able to bear his weight on it. There was a half-inch shortening but the leg was absolutely straight and in perfect position.

The case is reported because the fracture was oblique and comminuted, and because with the ordinary Buck's extension it had been impossible to force the fragments anywhere near apposition. The patient was a muscular, powerful man. I *do not believe that without operative interference* any sort of union could have been obtained. As will be seen from Figure 2, I used the largest size eight-screw plate. I have had smaller plates both bend and break in the treatment of transverse fractures of the femur in muscular men. I believe that in the femur, fixation is much better with the larger plate, *and the more absolute the fixation, the less likelihood there* is of irritation and of the plate's having to be taken out. The heaviest Sherman plates are good, but it seems to me that for the upper third, as in the case of this man, the heaviest plate made is not too heavy. The length of the plate permits racking of the ends, and warping out of the screws, so that *a long plate as well as a heavy one is desirable. Instead of* the two wires, if I had had them with me, I should have used the steel band of Parham and Martin, which they have designed for oblique fractures, but which might perfectly well be used in a case such as this in conjunction with a plate. The aid of Bartlett's clamp could hardly have been dispensed with in this case. The ordinary screws with their large thread I think are better than the fine-threaded Sherman screws.

In operating on smaller bones than the femur, smaller plates or even wire fixation may be used, and the effort may legitimately be made to use as small a foreign body as compatible with holding the bones.

527 Beacon Street.

Case of Swallowed Open Safty-Pin.—The following case seems to us to be sufficiently unusual and interesting to report: Evelyn S., aged 3, choked on an open, small-sized safety-pin at 6 p. m., Dec. 29, 1913. We failed either to see or to feel it under anesthesia, and referred her to Dr. Mersefelder of Canal Dover for roentgenoscopy. The rentgenogram showed a rather obscure shadow of the pin in the region of the stomach, the point unfastened and directed upward and to the right. The child went home for the night, but on account of soreness would neither eat nor drink. On the afternoon of December 30 we sent her to the Union Hospital and attempted to start forced feeding without catharsis. For the next twenty-four hours she would vomit everything she could be prevailed on to swallow, even liquids, although she was quite hungry. December 31, at 2 p. m., we passed a No. 26 catheter through the esophagus and into the stomach without encountering any unusual obstruction. Immediately afterward she ate ravenously without vomiting and without further trouble. The first bowel movement since the pin was swallowed occurred Jan. 2, 1914, at 9 a. m., and in it was passed the open pin firmly impacted in a large scybalum.—R. S. Barton, M.D., and H. A. Coleman, M.D., New Philadelphia, Ohio.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

The following dosage forms of an accepted proprietary article have been accepted for inclusion with New and Nonofficial Remedies:

CORPUS LUTEUM CAPSULES.—Each capsule contains desiccated corpus luteum, Armour, 0.3 Gm. (5 grains).

CORPUS LUTEUM TABLETS.—Each tablet contains desiccated corpus luteum, Armour, 0.13 Gm. (2 grains).

GRANULAR EFFERVESCENT SALICYLOS.—Pulvis Salicylatum Effervescens, Mulford.—This preparation has been accepted for inclusion with the appendix to New and Nonofficial Remedies.

A mixture said to contain in each 100 Gm. strontium salicylate 6.54 Gm. (24 grains per ounce), ammonium salicylate 6 54 Gm. (24 grains per ounce) with an effervescent base consisting of sodium bicarbonate and citric and tartaric acids.

Therapeutics

LECITHIN; EGG-YOLK

Phosphorus is such a necessary element in the perfect development and health of the cells of the body, and is so essential in the proper functioning of many parts of the body, especially nervous tissue, that any preparation said to present phosphorus in composition in assimilable form immediately causes clinical interest. Lecithin is a compound of phosphorus that is found in the organism, hence, when it was artificially prepared for administration in various diseased conditions, it became very popular, and was and is highly lauded as a treatment for all kinds of debility, anemias, nervous disturbances, mental diseases and neurasthenia.

In the first place, phosphorus is a constituent of nucleoproteins, and some kinds of phosphorized fats or lipoids, of which lecithin is an example. Phosphoproteins are contained in milk as caseinogen and in the yolk of egg as vitellin.

The discussion ever persists as to which elemental form is of greater value for the nutrition of the body, an inorganic salt or an organic combination. This is particularly true of iron and of phosphorus. It has been demonstrated almost beyond controversy that an ordinary person can metabolize an inorganic iron as readily and as perfectly as an organic iron, and this seems to be more or less true of phosphorus, administered in the form of phosphates or other salts. Also, it has been shown many times that organic phosphorus, as presented in milk or in eggs, probably changes in the body to phosphates, and from these salts it is elaborated into products as lecithin, so that there seems to be no physiologic or biologic reason for preferring isolated lecithin as a medicament to such a phosphorus-bearing food as the yolk of egg.

Phosphorus seems to stimulate metabolism, and often the person who receives phosphorus in any form seems not only to have an increased glandular and nervous activity, but also an increase in general nutrition. Phosphorus as an element, or such an active preparation as zinc phosphid, should rarely be administered as a medicament, as either irritates the gastro-intestinal canal, overexcites the glandular system, especially the liver, and causes more or less irritation of the kidneys. When the question is one of nutrition and the stimulation of the metabolism of the body as a whole, and not of a treatment to ameliorate a troublesome symptom, or of an antidote to any diseased condition, it seems inexcusable to administer drugs that may do harm.

The lipoid lecithins are phosphatids, and are substances of waxy consistence, soluble in alcohol, but insoluble in water. They are generally prepared from the yolk of eggs, probably are never quite pure, and contain about 4 per cent. of phosphorus. When lecithin is broken up it results in glycerophosphoric acid, a fatty acid, and cholin, which is a more or less poisonous nitrogenous base.

Under the influence of lecithin the number of red corpuscles and the hemoglobin content in anemic conditions may be increased. That lecithin is a "brain food," or is a stimulant to cerebral activity has never been proved. All statements to that effect are fallacious; in fact, there is no specific food for any part of the body. Certain nerve disturbances and certain cerebral and mental disturbances may at times increase the phosphorus output in the urine, and cause nucleoprotein, and, perhaps, lecithin disintegration; but the mere administration of lecithin, as such, could hardly be expected to improve such a condition.

The logical measure, when a physiologic nutritional phosphorus is desired, is the administration of egg-yolk. The yolk of the hen's egg is stated by Friedenwald and Ruhräh[1] to represent 49.5 per cent. water, 15.7 per cent. protein and 33.3 per cent. fat. The yolk of the egg is therefore rich in fat and protein, and has caloric as well as nitrogenous value. To obtain the activity of the lecithin content in the yolk of the egg it is perhaps best to administer the yolk raw. It certainly seems to be a fact that the administration of one or two raw or even cooked yolks of eggs per day would give a patient all the lecithin that he could metabolize, and present it in a better manner than in an artificial preparation. In any condition of debility, anemia or nervous disturbance the yolk of egg is as valuable as any or all artificial lecithins, or any preparation that combines nucleins and nucleoproteins.

It may be here stated, parenthetically, that the value of raw egg-white, or egg-albumin, as a nutrient has been very much overlauded, and dependence on egg-albumin as a food in serious conditions is a mistake. Egg-white has been found in some cases to pass very rapidly through the stomach without digestion, and to be incompletely digested in the intestine. Thus it may cause diarrhea, as well as fail to give nutrition.

DEATH BY FREEZING

It is scarcely necessary to explain to those engaged in the practice of medicine wherein the importance of ascertaining the precise cause of every death lies. Even if it were of no serious value to medical science (though in fact the contrary is unquestionably true), the legal aspects alone of the incidence of death present a strong plea for accurate, detailed and decisive knowledge regarding the demise of every member of the community. In the United States deaths from freezing form at most a very small proportion of the losses of life which require classification. As a rule circumstantial evidence must assist to make the determination of this mode of death comparatively easy, though alcohol and the rigor of climate are doubtless interwoven in many a case so as to render it difficult if not impossible to place the burden of immediate cause on the real factor. Death from freezing acquires a distinctly greater prominence, however, in countries like Russia, where the number of cases is reported to reach from 500 to 700 annually, and where in a single city like Riga the cause of death is attributed to cold at 9 per cent. of the medicolegal necropsies.

Reliable signs of death from undue cold are desired not only in those cases in which alcoholism may be a complicating and primary factor, but also in the case of a not inconsiderable number of new-born infants who are peculiarly susceptible to the fatal effects of the low temperatures prevailing in certain countries. Here the necropsy findings give little in the way of directive evidence. Most authorities in medicolegal matters have passed over the subject as one either devoid of serious interest or else unable to furnish a helpful solution.

The cause of death from extreme cold has been associated with a variety of pathologic consequences which doubtless cooperate in many instances. We may refer to the accumulation of carbon dioxid; the paralysis of the vagus nerve or of the vasomotor center; the undue loss of heat from the body; the engorgement of the heart with blood; an anemia of the brain; destruction of the red blood-cells, etc. None of these conditions leaves a record which can be deciphered as characteristic, if indeed it can be detected at all, at necropsy.

Dr. Krjukoff[1] of the Institute for Legal Medicine at the University of Moscow has reached the conclusion that the examination of the liver for carbohydrates will furnish a clue for discriminating between death from cold and death from other causes leading to a sudden end. Among the latter are included such circumstances as injury, asphyxiation, hanging, drowning, poisons, cardiac failure and other conditions in which life is precipitately terminated. Here there is little if any opportunity for nutritive changes, such as the transformation of the glycogen in the liver, to intervene. Cold, on the other hand, is a vigorous promoter of metabolic changes, particularly such as will liberate energy in the form of heat to conserve the threatened body temperature. Krjukoff argued that it is more than likely that the readily available carbohydrate of the liver would speedily and early be drawn on in the physiologic struggle to avert the impending catastrophe. This is at any rate in accord with evidence respecting the effect of lowered temperature on animals. In ten cases of death by cold (in man) glycogen was entirely lacking in the liver. In cases in which intoxication with alcohol was a factor, liver glycogen was still found present. The point of view here represented is based on reasonable physiologic considerations. More evidence is now needed to give some standing to this alleged characteristic sign of death by freezing.

TARTRATES AND NEPHRITIS

Our attention has lately been called to the advertisement of a well-known brand of "absolutely pure, cream-of-tartar baking-powder," in which the following passage occurs: "Cream of tartar is the crystallized acid of grapes refined to absolute purity and ground to a creamy flour. It is declared by physicians the most wholesome of all fruit acids." Without entering into a discussion of the partial incongruity of the definition which represents cream of tartar as a crystallized acid, we may still take issue with the remaining assertion respecting a product so widely used as are baking-powders of this class. It is, indeed, a matter of surprise *to find how little is known and recorded in the literature* with regard to the fate and physiologic action of some of the typical "fruit acids," among which are citric, malic, tartaric and benzoic acids, and their salts. The volumes to which the long-controverted question of desirable versus undesirable baking-powders has given rise have, strangely enough, not taken into cognizance some of the effects of tartrates which recent investigations have brought to light.

Many of the organic acids, like citric and acetic acids, are burned up in the body, giving rise to carbon dioxid and water. When their alkali salts are ingested, therefore, the end-product of their metabolism is alkali car-

---

1. Krjukoff, A.: *Beitrag zur Frage der Kennzeichen des Todes durch Erfrieren*, Vrtljschr. f. gerichtl. Med., 1914, xlvii, 79.

bonate. It is widely recognized that sodium citrate, for example, functions precisely like sodium carbonate in the organism. Other organic acids, notably benzoic acid, traverse the body unchanged; in the case here selected the substance introduced reappears, combined with glycocoll, in the form of hippuric acid. Physicians have not realized that tartaric acid and its salts are for the most part not destroyed in the body and leave it in their original form. Within the past few months several researches have brought into prominence the fact that tartaric acid and its salts under suitable conditions may give rise to symptoms of nephritis of varying severity.[1]

The investigators are agreed on the main features of the action of large doses of tartrates so far as they are observed to cause a pronounced disintegrative action on the epithelium of the kidney in animals. Associated with this there is noted to be a greatly diminished volume of urine and a marked decrease in the elimination of certain of the urinary constituents. The severe renal disturbance may be attended by the excretion of protein and casts when there is not complete anuria. Such sequences are described for various forms of administration of the tartrates, by mouth, intraperitoneally or subcutaneously. According to Underhill and his colleagues, the changes induced in the kidney are confined almost exclusively to the tubular epithelium, and they even believe incidentally that this fact will afford a means of studying various phases of defective renal secretion with practically intact glomerular structure. The Philadelphia investigators, Pearce and Ringer, agree in describing the striking histologic change in the kidney as a defect of the convoluted tubules, with fatty changes in the loops of Henle and sometimes also in the collecting tubules. On the other hand, they report exudative glomerular lesions in about half of the subjects with severe tubular lesions. In the disintegrative changes taking place, vacuolation first occurs, is rapidly followed by necrosis and finally the dead cells or their débris may entirely fill the lumina of the tubules and form granular and hyaline casts. Neither the liver nor the adrenals exhibit any pathologic defect attributable to the tartrates in such cases.

The mode of administration to animals does not influence the character of the renal lesion, except that diarrhea, following administration by mouth, may cause rapid removal of the harmful salt from the intestine, and thus prevent the severer types of lesion by reducing the extent of absorption. No strict relation between the dose of tartrate and the extent of damage inflicted has yet been made out. A varying resistance or degree of tolerance seems to hinge on the character of the diet, when tartrate is given by mouth. In well-fed animals the pathologic changes induced by feeding the salts of tartaric acid, though distinct, are less in degree than those which are provoked by the same dose in starvation. There is even evidence that the actual state of nutrition plays some part in the development of tartrate nephritis.

Underhill, Wells and Goldschmidt[1] have noted that histologically there is evidence that the administration of alkali exerts a slight modifying action, presumably permitting a readier elimination of urinary waste-products. It is deserving of emphasis that the observations on tartrate nephritis are not in harmony with the widely discussed hypothesis of Fischer.[2] He has mentioned tartrates, among other salts, as being of value in the prevention of nephritis — a dangerous statement in view of the foregoing evidence to the contrary. Probably, as Underhill and his colleagues suggest, Fischer, like many others who generalize in physiology, assumed that tartrates are readily burned to carbonates in a manner similar to certain other salts of organic acids discussed above.

It would be unwise to magnify the dangers of tartrate in the face of their long use in baking-powders, in the well-known purgative mixtures like Seidlitz powders and Rochelle salt, and their actual occurrence in foods. But when we are reminded that in certain instances of chronic kidney involvement cream-of-tartar water is often prescribed for the promotion of diuresis, and that the use of tartrate purgatives is tending to be overdone in many quarters, it is time to inquire into the possibility of unsuspected dangers. If the benzoates are condemned, shall the tartrates be condoned? Some help toward an answer to this question, so far as it involves the practical use of tartrates in clinical medicine, is given in the article by Post,[3] published elsewhere in this issue of The Journal. He has demonstrated that when potassium and sodium tartrate is given in ordinary doses by mouth to human subjects it need not cause albuminuria or cylindruria; nor is there any evidence to show that tartrates aggravate an existing nephritis in his clinical experiments. Post points out that the harmful doses used by the experimenters on animals would be equivalent to nearly 7 ounces in a man weighing 150 pounds. This is, of course, incomparably greater than the clinical dosage, which ranges from 1 to 6 drams. The fact that the administration of tartrates, even in nephritis, is not necessarily inconsistent with safe clinical practice, is thus reconciled with the pronouncedly harmful effects noted in the laboratory experiments. The dosage is apparently the decisive factor.

THE MODIFICATION OF SECONDARY SEXUAL CHARACTERS

The belief that the so-called secondary sexual characters are in large measure dependent for their appearance on an influence exerted by the genital glands on the other parts of the reproductive apparatus and on the body generally is not a new one. Castration carried out before the time of puberty prevents the development of these secondary sexual characters, which occurs at this epoch in both sexes. Castration after puberty, though not causing any pronounced changes in the skeleton which has already assumed a permanent form, brings about retrogressive manifestations in the remaining genital organs analogous to those occurring in the female at the climacteric. There was a time, not long since, when these interrelations were supposed to be controlled by nervous connections between the genital glands and the rest of the body. To-day there is a rapidly growing conviction that the secondary sexual characters must be ascribed to the influence of chemical substances—genital hormones—produced in the ovaries and testes, respectively, and distributed by the bloodstream. We are here dealing with another of the many evidences of "internal secretions" of specific glands.

Far more convincing and characteristic than mere extirpation experiments, such as castration exemplifies, are the results of the transplantation of genital organs. Some time ago we reviewed the striking results of Steinach[1] in this field of study. They showed the peculiar effects which transplantation of ovaries and testes into young castrated animals of opposite sex could actually bring about. The potential males became converted after this exchange of genital glands into individuals of unmistakable femininity which manifested itself in the modification of form and in the deportment of the animals. The inherent impulse in the direction of a distinctive secondary sexual development, in which physical features and habits of behavior are preeminently characteristic and specific for each sex, can be completely checked and reversed, so to speak, under the influence of the type of genital glands which is permitted or compelled to survive in a youthful organism. Even the psychosexual traits are modified in accord with the sort of gland that the individual is experimentally made to harbor.

Now, however, Steinach[2] has gone still farther in demonstrating the profound influence of the genital glands. He has carried the observations far beyond the stage of puberty. The preponderance, if not the consensus, of opinion at the present moment ascribes the hyperplasia of the mammary gland and the inception of milk secretion attending pregnancy to hormones which have their start in the developing fetus or in the placenta. Steinach has noted that if the transplanted ovaries find a firm foothold and succeed in maintaining their nutritive equilibrium in his "feminized" males the development of the female sexual characters is even accentuated. The growth alterations ordinarily expressive of masculine features are inhibited so markedly that the female type becomes more conspicuous than ever. The rudimentary mammary organs, always present in the male as in the virgin female, may develop to a stage characteristic of the pregnant female. We learn the remarkable fact that the surprising hyperplasia of the mammary glands and their appendages may readily reach a stage at which typical milk, not mere exudate, is secreted in abundance. Steinach reports cases among his experimentally "feminized" males in which they not only have adopted the traits of maternal females, including a tolerant attitude toward young animals of the same species placed with them, but also have suckled the young animals.

These startling observations suggest that the significant influence of the ovary in determining and modifying character in the direction of developing the feminine type is not finished with the changes that are completed at puberty, but extends far beyond into the periods when lactation is involved. But Steinach and the roentgenologist Holzknecht have gone even farther. They have attempted to stimulate the ovary of the normal virgin female so as to cause it to induce some of these changes just described as evoked by the overactive transplanted ovaries. By suitable exposure of the region of the ovaries to the Roentgen ray, the juvenile, virgin characters were made to disappear in the non-gravid female, and to be superseded by the phenomena of lactation — enlargement of teats, hyperplasia of the mammae, secretion of normal milk and hypertrophy of the uterus.

By a comparable procedure of testicular transplantation it appears to be possible to induce the exhibition of masculine traits and features in the castrated female. Sex characters are therefore not fundamentally determined in advance throughout all the parts of the organism that ordinarily give exhibition of distinctive features; otherwise it would be impossible to remodel the sex-determined disposition of an individual so profoundly by an exchange of genital glands.

The sum total of the foregoing observations tends to confirm the view, expressed by several authors,[3] that the essential factors for the production of the genital hormones are the "interstitial" cells found in both the testes and ovaries of various animals. The genital glands are thus believed to contain gland-cells of two distinct and functionally independent types. These interstitial cells, however, are apparently not universally present. It has been shown that, by means of the Roentgen rays, it is possible to destroy the germ-cells in either testes or ovaries, so rendering the animals sterile. Whether the interstitial cells, which are not destroyed by these rays, are the originators of the unique effects in respect to secondary sexual development and the awakening of mammary activities remains to be determined. It is at length becoming probable, from the experimental researches of the past few years, that we shall presently see remarkable developments in the direction of influencing some of the functions hitherto regarded as beyond the pale of physiologic or therapeutic modification.

CARDIAC AND RENAL DYSPNEA

The question of the controlling factors in the regulation of respiration has furnished one of the long-debated topics of physiology. Excess of carbon dioxid and deficiency of oxygen in the circulation have each been credited with being the effective agent in promoting increased respiration. The trend of recent investigation has tended to show that each of these may represent a factor of moment, inasmuch as the respiratory center can be excited by either condition; but it has now been established, in particular by the studies of Haldane and his pupils in England, that the sensitivity of the center to carbon dioxid is by far the more important feature of the increased respiratory movements in asphyxia. Indeed, it is the only chemical factor which can at present be regarded as playing any important part in the regulation of the respiratory movements under normal conditions.

The acquisition of a fundamental chemical basis for the understanding of the processes by which respiratory activities are controlled has made it far easier to investigate the pathology of respiration intelligently. In the clinic one encounters various types of dyspnea which cannot be relieved properly until there is some adequate appreciation of the underlying disturbance. Forms of breathlessness are common to certain cardiac and renal patients, and lately a clear-cut distinction has been pointed out between the degree of breathlessness and the degree of cyanosis in certain groups of cases. It is well known that there are many persons who suffer at times from an underaeration of the blood. In these persons a blue tint is a conspicuous manifestation. This may occur in forms of congenital disease of the heart in which the venous blood is in part short-circuited by the lungs and returned to the arterial system in an unaerated condition. The dyspnea of the patients who show deep cyanosis is not always great; in fact, the deficient aeration has sometimes to be considerable before urgent dyspnea is exhibited. On the other hand, we are told by investigators who have given careful consideration to these problems that although a proportion of those heart patients who suffer from labored breathing show what may be termed deep cyanosis, yet a large, if not equal number, though breathless, are far less blue.[1] They remark that in extreme instances the breathlessness of a patient may be urgent, yet cyanosis may be slight or even absent. Obviously, a person who suffers from deficient blood aeration, that is, oxygen deficiency, must inevitably be blue; but when there is no cyanosis to suggest a cause for the breathlessness, some occasion for the dyspnea other than the purely physical relations of blood and air in the pulmonary alveoli must be found, for in such cases there is no evident deficiency in aeration. In these instances an additional cause for the more vigorous movements of respiration has been found by the English investigators in the relative acidity of the blood.

A new aspect is thus given to breathlessness, and especially cardiac dyspnea. When cyanosis, the index of deficient aeration, is sufficiently pronounced, this will of itself account for the labored breathing; otherwise acidosis must be called in to account for this symptom. The explanation naturally suggests itself that if the dyspnea of this type is not due to a lack of oxygen it may be accounted for by the second factor already discussed, namely, an accumulation of carbon dioxid caused by stasis. Blood analyses in the selected cases, however, show that it is not the result of excess of carbon dioxid in the blood.

How are we to account for an abnormal excess of acids other than carbonic acid over the bases of the blood — in other words, for the acidosis here presented and sufficient to act as a stimulus to the respiratory center which is so sensitive to acid conditions of any sort whatever? Investigation has shown that, in the cardiac cases at least, the condition of acid intoxication is not due to beta-oxybutyric acid, the compound which arises in such abundance in severer forms of diabetes. There is little evidence, furthermore, that lactic acid, another product of incomplete oxidation, is a prominent cause of the difficulty. The acidosis, as the English investigators believe, appears to be another instance of the phenomenon of retention of acids in excess of bases, perhaps because of a failure of the kidneys in respect to the excretion of acid. If this explanation should be found sufficient, the condition would admit of simple treatment by giving a diet rich in bases or base-yielding foods.

In the past there has been considerable confusion in the use of the expressions "cardiac asthma" and "renal asthma" or "uremic dyspnea." In the latter class the predominating lesions are renal, whereas in cardiac asthma the heart seems to be the seat of the difficulty. Lewis and his colleagues[1] regard it as probable, though it cannot be held as finally proved, that there is no essential difference between "cardiac" and "renal" asthma, so-called, and that the dyspnea of the cardiac cases, when neither anemia nor cyanosis is conspicuous, arises in the majority of cases from acid intoxication and is in reality due ultimately to renal defects. This does not exclude other instances of pure cardiac cases in which excessive accumulation of carbon dioxid in the blood sufficiently accounts for its reaction and the respiratory stimulus.

REFLECTIONS REGARDING CHOLESTEROL

Inasmuch as the newer researches concerning the intake and output of cholesterol in the body give little evidence of any new formation of this important compound in the organism of the higher animals, information regarding the ways in which the supply of this lipoid is altered must be heartily welcomed. Cholesterol has long attracted attention because it occurs pathologically not only in the familiar form of gall-stones, but also in tissues the cells of which are undergoing slow destruction and in which absorption appears to be poor. It is also frequently found in atheromatous patches in the blood-vessels, encapsulated caseous areas, old infarcts and hematomas, inspissated pus collections, dermoid cysts, hydrocele fluids, etc.; and in the cholesteatomatous tumors of the ear and cranial cavity. But such occurrences of cholesterol are, perhaps, of secondary moment in comparison with the rôle which it plays in the behavior of the blood-corpuscles and the numerous phenomena connected with so-called immunity reactions, all of which are a decidedly modern aspect of biochemical study. The specific blood-tests may be cited as illustrative of the various processes in which cholesterol and other lipoids have been demonstrated to be seriously involved. No earnest discussion of serologic work can be undertaken to-day without reference to them.

With the biologic importance of cholesterol thus plainly emphasized it seems incumbent to follow its history in the organism and to learn its physiologic and pathologic migrations and fate as thoroughly as may be possible by present-day methods. It seems more than probable to-day that the cholesterol of the blood is normally so distributed that the cellular elements contain the compound in its free state. The leukocytes are far richer in cholesterol than are the red corpuscles. In the blood-serum, on the other hand, cholesterol is found both free and in the form of its fatty acid esters. Broadly speaking, the cholesterol content of the blood of normal individuals appears to be constant under fixed conditions of diet and living. It can be enhanced by feeding cholesterol as such, whereby both the free cholesterol and its esters are increased in quantity in the circulating medium. Subcutaneous administration of cholesterol likewise brings about its augmentation in the blood-serum. The corpuscles are affected slightly, if at all, by such enrichment of the medium in which they float. Wacker and Hueck[1] have made the added discovery that long-continued administration of liberal amounts of cholesterol may lead to an increase not only of its derivatives, but also of other lipoid substances. It may be deposited in various organs, such as the liver, kidney, spleen, bone-marrow, gall-bladder, adipose tissue, etc. A point may be reached at which cholesterol depositions occur in the mucosa of the gastro-intestinal tract; they may even occasion a diseased condition of the aorta which in many ways resembles the features of arteriosclerosis in man.

The knowledge of the possibility of modifying the cholesterol content of the tissues of the body by the regulation of its supply opens unsuspected possibilities in directions which can be only inadequately foretold at present. We need but refer to the reputed relation of cholesterol to growth, particularly so far as it involves the development of neoplasms. Robertson and Burnett[2] have asserted that cholesterol accelerates the growth of carcinoma in rats and may be a factor in the incidence of cancer. According to Burnett, it has an accelerating action on malignant tumor growth, whether it be injected into the tumor or carried to it by the circulation. If it prove true, as now is maintained by various investigators,[1, 3] that cholesterol is not synthesized by animals, the cholesterol in their tissues being derived from the diet, the possibility is suggested of diminishing the incidence of carcinoma in inoculated animals by feeding them for a considerable period prior to the inoculation on a diet poor in cholesterol. Experiments have failed as yet to substantiate this hypothesis. Robertson and Burnett, however, have called attention to the fact that animals tend to conserve and accumulate cholesterol, and Wacker has noted an excessive content of the substance in the reserve fats of aged persons. It has been surmised, accordingly, that this in turn bears a relation to the well-known increase in the incidence of carcinoma with advancing age.

For the moment it matters little whether the facts keep pace with the hypotheses in the restricted domain of application which cholesterol biochemistry has thus far found in connection with cancer research. Our aim here is primarily to point out that when more knowledge is accumulated respecting the source and fate of cholesterol in the organism it is certain to have important biologic applications. Already it is becoming apparent that the cholesterol supply of the body can be demonstrably affected by dietary or therapeutic measures, and that cholesterol is no fortuitous component of the organism.

Current Comment

EDUCATIONAL LECTURES ON MUNICIPAL HYGIENE

Most of the leading educational agencies of the present day recognize the value of the personally delivered message as a means of educating and influencing public opinion. The editorial, the pamphlet, the cartoon and the exhibit have a definite worth, but none of them seems to compare in effectiveness with the spoken message of an authoritative speaker. Some form of speakers' bureau is a recognized part of all successful educational campaigns. The department of social development of the Brooklyn Bureau of Charities has organized a speakers' bureau to supply lecturers on municipal problems. A directory of the men available shows a large number of well-known and recognized authorities on such subjects as women's wages, industrial accidents, old-age insurance, child labor, housing, disease prevention, foods and drugs, preventive medicine, outdoor recreation, causes of crime and vice, liquor problems, care of the insane and feeble-minded, city beautification, immigration, etc. These subjects are to be discussed from the special point of view of the New York citizen rather than in a general way. Such an educational campaign is characteristic of present-day ideas and ideals of social progress, and cannot fail to have a beneficial effect on social conditions.

THE AMINO-ACIDS IN THE BLOOD

With his characteristic energy and ingenuity the German physiologist, Emil Abderhalden, has at length succeeded in demonstrating the presence of amino-acids in the serum of the blood by the direct isolation and identification of a number of these protein derivatives.[1] That amino-acids are to be found in the circulating blood could scarcely be doubted since the exploratory work of Van Slyke and Meyer, Folin and others in this country has pointed to the probable absorption and distribution of the products of protein digestion in the form of amino-acids. There have long been evidences of the existence of non-coagulable nitrogenous compounds other than urea in the blood. The analytic figures, however, show that the residual margin for this type of derivative is very narrow, and that the content of such substances circulating at any moment in the blood-stream must be extremely small at best. Abderhalden has outdistanced his predecessors by working on a large enough scale, literally with dozens of gallons of blood, to succeed in separating the actually occurring products as such. One is reminded here of the enormous task which Krüger and Salomon[2] undertook some years ago when they analyzed 10,000 liters of urine in order to determine the nature of the small quantity of purins other than uric acid which are ordinarily found in the secretion of the human kidney. The thought of a university chemist manipulating from 50 to 100 liters of blood at a time reminds one more of a factory than of a physiologic laboratory. It was by such heroic efforts, however, that small quantities — not more than 0.4 gm. of pure substance in any single instance — of the following amino-acids were obtained and identified: prolin, leucin, valin, alanin, glycocoll, aspartic acid, glutaminic acid, arginin, lysin and histidin. Even in starvation the blood was not found entirely devoid of amino-acids, so that Abderhalden suggests the possibility that the amino-acid content of the blood may perhaps be kept at a constant level somewhat as is its quota of sugar. The future may accordingly find it appropriate, as he remarks, to speak of a hyper-amino-acidemia or hypo-amino-acidemia representing specific alterations in the level here referred to. No sooner have we recorded one evidence of progress in this field of research[3] than another step in advance is ready to be told.

THE VORACITY OF CERTAIN DIABETICS

Through the recognition of the intimate relation of the sensation of hunger to contractions of the empty stomach, which may now be accepted as an established physiologic fact,[4] the nature of the polyphagia which attends certain conditions of disease may now be investigated. The great voracity of animals suffering from pancreatic diabetes is well known to laboratory workers. In man, comparable polyphagia is sometimes seen in the course of diabetes mellitus or marasmus arising from other causes. The accentuated desire to eat cannot be ascribed to the state of existing undernutrition alone; for it is usually missed entirely in numerous other even more extreme cachexias in which food is persistently refused. Recent observations of Luckhardt[5] at the University of Chicago clearly indicate that in the diabetic state the polyphagia is attributable to true hunger rather than to some perverted appetite induced by the condition involved. A comparison of the contractions of the stomach before and after operative removal of the pancreas in dogs shows that the gastric contractions not only persist with singular vigor after the operation, but become even more intense with the progress of the induced disease, just as the voracity of the patient increases during the terminal stages of the disease. Accordingly, the desire for food is the result of true hunger pains brought about by real hunger contractions of the stomach. Luckhardt notes the surprising fact that the smooth musculature of the stomach shows an untiring activity at a time when the skeletal musculature of the body is becoming extremely susceptible to rapid fatigue; in fact, the strength of the gastric contractions has been seen to increase as the power of the voluntary musculature is diminished. We are here dealing with a desire to eat in no wise attributable to a morbid longing for food or a perverted appetite.

SURGEON-GENERAL OF THE NAVY

February 7, in accordance with his policy of making appointments for one term of four years, Secretary Daniels sent the name of Medical Inspector William C. Braisted to the Senate to succeed Dr. Charles F. Stokes as Surgeon-General of the Navy. Secretary Daniels said further,[1] in a tribute in which we join, "Dr. Stokes has completed a four-year term of able administration, during which he has effected many important and beneficial changes; he has brought the bureau of medicine and surgery, the naval hospitals, and ships' medical departments to a high standard of efficiency. The Secretary has the highest opinion of the ability and splendid service rendered by the retiring Surgeon-General. Under his administration important reforms have been inaugurated. Never has the standing or reputation of the medical corps of the Navy been so high as it has reached under the administration of Dr. Stokes." The new Surgeon-General was born in Ohio, Oct. 9, 1864, and entered the Navy as an assistant surgeon in 1890. He was recently promoted to his present rank of medical inspector and has been serving as fleet surgeon of the Atlantic fleet.

PRACTICAL EUGENICS

The extent to which the good and bad qualities of one generation are transmitted by heredity to another generation is an unsettled question; but there is no doubt that the conditions surrounding the fetus *in utero* have much to do with the vigor with which it enters on its extra-uterine life. Prenatal care of the mother is a logical extension of the philanthropy which is seeking to conserve the vital resources of the nation by the care of infants. Provision for such antenatal care has been made for the past four years by the Committee on Infant Social Service of the Women's Municipal League of Boston, and its example has been followed in a number of other cities. The committee now has made its report for the first four years of its existence with statistics for a part of the fifth year. The work of the committee has been restricted to the visiting of pregnant women once in ten days by a competent nurse, who takes blood-pressure, examines urine and advises regarding diet and regimen, but gives no drugs, with the exception of cascara. The success of the work is judged by the decreasing frequency of eclampsia, stillbirths, premature births, and by the increase in the weight of the babies. In all these particulars they record a steady improvement as the result of prenatal care. Thus the figures for percentage of cases of threatened eclampsia for the first four years are, respectively, 10.2 per cent., 4.8 per cent., 1.7 per cent. and 0.0 per cent. The percentage of stillbirths fell from 2.6 per cent., the average for three years, to 1.7 per cent. for the fourth year. The corresponding figures for the premature births were 1.7 per cent. and 0.7 per cent. A slight increase in the average birth-weight is also recorded. These figures, the committee believes, present sufficient evidence of the effectiveness of prenatal care to justify the continuance of such work. The expense is slight, amounting to about three dollars a year per patient. It is intended to extend this treatment to private patients, the nurse reporting to the family physician instead of to the hospital, as is the case with the public work.

DOCTORS CAUGHT IN AN ANTISPITTING CAMPAIGN

The recent article by Stiles,[1] concerning the carelessness of some physicians in matters of hygiene, has been attacked from various sources as being too caustic and as exaggerating the facts. In Chicago recently an antispitting campaign was inaugurated by the police and health departments. Instructions were given to the police to enforce one of the various antispitting ordinances. The results of a day's campaign are thus reported in one of the Chicago dailies:

> Two physicians, Dr. O. H. B——— and Dr. A. H.———, were fined $2 and costs each by Judge Sabath yesterday for spitting. Seventy other men were fined $1 and costs. One was fined by Judge Dolan. Twenty-five were fined by Judge Goodnow in Hyde Park and three in Englewood. Dr. U. G. D——— spat on the floor of a State Street car at Forty-Seventh Street. A patrolman was riding on the car and arrested the physician.

On the other hand, it is reported that a conscientious policeman who caught himself in the act of expectoration took himself to the court and paid his fine.

THE ESTIMATION OF ACIDOSIS IN DIABETES

The symptoms of acidosis are at present commonly taken as indicating the direction of treatment and the prognosis in diabetes. The question as to what features of the acidosis complex should serve as a guide arises frequently. The estimation of one or more of the "acetone bodies," that is, the determination of the degree of ketonuria, has been taken into chief account by some students of the subject. It must be remembered, from the standpoint of the acid-intoxication theory, that acetone, aceto-acetic acid, and beta-oxybutyric acid are not identical in their mode of behavior. It has now been demonstrated repeatedly that the pressure of carbon dioxid in the alveolar air falls with the increasing acidosis of diabetes, rises under the administration of an alkali like sodium bicarbonate, and during coma reaches a very low point. Kennaway, Pembrey and Poulton[2] have come to the conclusion that the estimation of the alveolar pressure of carbon dioxid by Haldane's method is at present the best guide in the prognosis and treatment of diabetes. Diabetic patients discharging large quantities of sugar in the urine may have a normal value for the alveolar carbon dioxid; the determining factor appears to be the extent of acidosis. Estimations of the total acetone bodies are not of such importance from the prognostic point of view, for the variations in the absolute amounts do not run parallel with the alveolar carbon dioxid and give no indication of the onset of coma. The chief drawback at present to estimating the degree of acidosis by the alveolar carbon dioxid tension lies in the fact that it requires a special technic which, at present, few clinicians have mastered.

Medical News

ALABAMA

New Officers.—Mobile County Medical Society at Mobile, January 31: president, Dr. Ruffin A. Wright; secretary, Dr. Willis W. Scales, both of Mobile.——Clarke County Medical Society at Grove Hill: president, Dr. Isham Kimbell, Jackson; county health officer, Dr. John A. Kimbrough, Thomasville.——Marshall County Medical Society: president, Dr. Phocion B. Lusk, Guntersville; secretary-treasurer, Dr. William E. Noel, Boaz.

Personal.—Dr. Charles A. Grote of the State Board of Health has been studying the work of the North Carolina State Board of Health at Raleigh, and also inspecting the methods of the local boards of health at Asheville and elsewhere.——Dr. Robert B. Hays has left Woodward and accepted a position with the Birmingham Infirmary.——Patients, former patients and friends of the Lynnhurst Sanatorium presented Dr. Ante Costa Watts, Birmingham, the medical director, with a microscopic outfit.——Dr. William M. Caffee, Birmingham, who was operated on recently for appendicitis, has recovered.——Dr. Marion T. Davidson, Wylam, was seriously burned by an explosion of chemicals in the Wylam Hospital, January 30.

ARKANSAS

Sanatorium to Open.—Drs. Malcue G. Thompson and Murray G. Thompson, Jr., Hot Springs, will open a sanatorium at Ashdown in the New Sanderson Building.

New Officers.—Pulaski County Anti-Tuberculosis Society at Little Rock, January 30: directors, Drs. Charles W. Garrison and Orange K. Judd, both of Little Rock.

Health and Vital Statistics Laws.—Until a year ago Arkansas had no state board of health. A law was enacted by the legislature at that time creating a board of health and also providing for the registration of vital and morbidity statistics through state and local registrars. This legislation is in accord with the model law approved by the Census Bureau, the American Public Health Association and the American Medical Association, and places Arkansas in line with the progressive states in respect to health legislation. In commenting on this and the active health propaganda which has characterized the last decade, the *Arkansas Democrat* says concerning the new health department: "An entirely new conception of public duty has been forced on our lawmakers in this respect, and now for the first time in the history of Arkansas, our vital resources—men, women and children—are to receive the same governmental care and protection as our soil, rivers, forests, hogs, cattle and horses. Ten years ago it would have been impossible to pass the law under which the new State Board of Health is operating, notwithstanding the fifty years of successful experience in New York, Pennsylvania and Massachusetts in public health administration. It has taken years of energetic, unselfish and unremitting effort to bring the Southern states to a commitment of the truth that the protection of the public against preventable disease is a fundamental duty of state government."

ILLINOIS

Hospital Dormitory Plans Ready.—Plans for the dormitory addition to St. Joseph's Hospital, Elgin, have been completed, and work on the building will begin early next month. The cost of the addition will be approximately $25,000.

Personal.—Dr. David Lieberthal has resigned as professor and head of the department of dermatology and syphilography of Bennett Medical College.——Dr. Samuel Amberg of the Otho S. A. Sprague Memorial Institute, Chicago, has been elected a corresponding member of the Society of Internal Medicine and Pediatrics, Vienna.——Dr. C. Max Hawley, assistant superintendent of the Watertown State Hospital, has been transferred to a similar position at the Elgin State Hospital.——Dr. Clesson C. Atherton, physician to the Lincoln schools, has been appointed assistant superintendent of the Watertown State Hospital.——Dr. Wilson K. Dyer of the staff of the Watertown State Hospital, has resigned to take up private practice.

INDIANA

Laboratory Incorporated.—The Fort Wayne Medical Laboratory has been incorporated with a capital of $5,000, by Dr. Bonelle W. Rhamy, Mary Rhamy and Robina L. Orvis.

Personal.—Dr. Quincy M. L. Williams, Folsomville, was shot and seriously wounded by his brother-in-law, February 5, as the results of a family feud.——Dr. Herman H. Kamman, Columbus, was knocked down by his motor-car, February 3, fracturing two of his ribs——Dr. John W. Cook, Pendleton, is reported to be critically ill with pneumonia.

Small-Pox in Indianapolis.—During January there were 83 cases of small pox in the city, and during February the disease has increased to such an extent that an order compelling vaccination of all schoolchildren, under penalty of exclusion from the schools, has been issued by the Health Department. It is said that the small-pox situation is costing the city $100 a day.

Trachoma in Bartholomew County Schools.—Trachoma was found to exist in twenty schools, in eight townships, one town, and one city. Forty-eight cases of well-marked trachoma were found in the 3,969 schoolchildren examined, or 1.2 per cent. Twenty cases of trachoma were found in eleven county schools and one township consolidated school. Fourteen cases were found in six Columbus schools, eleven cases were found in the East Columbus consolidated school, and three in the high school, town of Hope. In the country schools, six cases were found in one school in Wayne Township. For the above it will be noted that trachoma is most prevalent in the two townships, Columbus and Wayne. Thirty-four cases were found to exist in these two townships.

KANSAS

New Officers.—Harper County Medical Society, at Anthony, January 28: president, Dr. George S. Wilcox, Freeport; secretary, Dr. Horace L. Gallaway, Anthony.

State School in Quarantine.—The Kansas State School for the Blind, Kansas City, has been closed and quarantined by the state health officials on account of the presence of a case of small-pox.

Personal.—Dr. Uriah I. Ward, Hutchinson, fell on the sidewalk at the Masonic Home, Witchita, January 25, suffering a compound fracture of the hip.——Dr. Roscoe T. Nichols, Liberal, has been appointed student physician to the State Agricultural College, Manhattan.——Dr. T. H. McLaughlin, for the last fourteen years a medical missionary in Africa, has returned to the United States to resume practice in Topeka.

KENTUCKY

Trachoma in Louisville.—Drs. Oakley and Moore of the United States Public Health Service, who have been investigating trachoma in Kentucky, report that they have found 176 cases among 4,558 children examined in the county outside of the city. In Louisville 450 cases have been found in the schools.

Small-Pox in the Legislature.—Senator Porter, a member of the legislature is reported, under date of February 4, to have small-pox, and a conference of legislators was held with the State Board of Health for the adoption of measures to prevent its spread. It is said that a number of the members have not been vaccinated.

Personal.—The following members have been added to the staff of the St. Elizabeth's Hospital, Covington: Dr. John L. Phythian, Newport, and Drs. R. W. J. Irtel, Josiah G. Furnish, Elmore B. Backsman, Newport; Charles G. Preck, H. Clay White, O. Lyle, Reynolds, and Michael M. Behrman, Covington.——A fire in Covington, February 4, destroyed the office of Dr. Charles A. Nevitt.

Preventable Diseases.—In the biennial report of the State Board of Health, it is shown that in the thirty-three months of the operation of the vital statistics law there have been reported 169,854 births, 83,778 deaths, of which 33,866 were due to preventable diseases. For each of the deaths reported, there were twenty-six cases of illness from the same cause, 541,856 illnesses which should have been prevented.

MARYLAND

New Hospital.—Ground has been broken for the new South Baltimore Eye, Ear, Nose and Throat Hospital on Light Street, to cost $50,000 and to have about fifty beds. The hospital was started twelve years ago by Drs. Harry E. Peterman and James Boardley and much charitable work has been done since its opening.

Small-Pox in Baltimore.—An additional quarantine hospital for small-pox cases was established February 10, near Texas, Baltimore County. There were 75 well developed cases of small-pox in the county; 40 were being cared for in the City Quarantine Hospital, and an equal number of suspected cases were under observation at the Sydenham Hospital.

Must Report Sore Eyes.—An ordinance requiring physicians to report to the Health Department within twelve hours after diagnosis all cases of sore eyes among infants and children was introduced in the second branch of the Baltimore city council by Dr. George Heller. This bill was introduced that steps to lessen blindness might be taken. Epidemic meningitis and infantile paralysis were also added to the list of contagious diseases reportable to the Health Department.

Personal.—Dr. Fred Caruthers, Baltimore, formerly coroner of the Northeastern district, was operated on at the Franklin Square Hospital for tetanus resulting from blood poisoning, which occurred two days after an ulcerated tooth had been extracted. Dr. Caruthers was reported as slightly improved, but his condition is still serious.——Dr. Charles L. Mattfeldt, Catonsville, who has been a patient at St. Agnes' Hospital for the past ten days, is improving.——Dr. Harry Adler, Baltimore, slipped on a rug last week at the home of his father and broke his leg just above the ankle.—Dr. Charles Bagley, Jr., who has been associated with Dr. Harvey Cushing at the Peter Bent Brigham Hospital, Boston, Mass., has resumed practice in Baltimore.

Report of the Mental Hygiene Committee.—The Mental Hygiene Committee completed a highly successful first year on January 7. The objects of the committee are set forth under the following headings: (1) Prevention of nervous and mental breakdown by early treatment, practical advice and material assistance, when necessary. (2) After-care and reestablishment in the community of patients discharged or paroled from state hospitals. (3) Social service in cooperation with organized and private charity and the hospitals. (4) To familiarize the public with the causes and means of prevention of mental disease, feeble-mindedness, delinquency and criminality. (5) To do and effectuate everything possible to improve and elevate the standard of care for the mentally afflicted in Maryland. During the year 320 cases have been referred to the committee from the following sources: Springfield State Hospital, Spring Grove State Hospital, Rosewood State Training School, Crownsville State Hospital, Supervisors of City Charities (Bay View), Phipps Psychiatric Clinic, Sheppard and Enoch Pratt Hospital, Juvenile Court, Bureau of Statistics and Information, Magistrates Dean, Supplee and Sayler, and the Northeastern, Central and Western Police Stations, the Federated Charities, St. Vincent de Paul Society, Henry Watson Children's Aid Society, Federated Jewish Charities, Lunacy Commission, private physicians and others. All the state societies in which there is a Mental Hygiene Committee will hold a meeting in Baltimore May 25. The following states will be represented: Massachusetts, New York, Illinois, Connecticut, Pennsylvania, North Carolina and Maryland, and the National Committee for Mental Hygiene.

Recommendations for Health Service Administration.—Surgeon Carroll Fox, U. S. P. H. S., after investigations carried on for a period of six months, has made elaborate and important recommendations for the administration of the State Public Health Service. Among these recommendations were: that the state be divided into not less than ten districts, each district to be placed in the charge of a physician trained in sanitary science, assistants, nurses, inspectors and a clerk; that the duties of these district sanitarians be well defined, and include supervision of the work of all health officers, enforcement of laws, inspection and investigation of nuisances, and such other duties as may be required of him by the state; that incorporated towns, and towns not incorporated, of more than 1,000 population be required to appoint a health commissioner to assist the district health officer in the enforcement of his duties; that each town be required to put aside 2 per cent. of its available funds to be devoted to the betterment of the public health; that comprehensive laws be enacted making it compulsory that plans providing for water-supply, sewerage and refuse disposal systems be approved by the State Health Department; that special attention be given to the sanitation of public schools; that a statewide campaign be carried on against typhoid fever; that a study be carried on by the state of pellagra, trachoma, hookworm, infant morbidity and mortality, and malaria; that laws be enacted for factories, stables, hotels, restaurants, etc., and that the maintenance of the sanitation of dairies, milk-supplies, etc., be taken from the hands of the State Live Stock Sanitary Board and be placed in the hands of the State Department of Health.

MASSACHUSETTS

Personal.—Dr. Conrad Bell has succeeded Dr. C. Richard Bell as member of the Board of Health of Waltham.——Dr. John T. Reynolds has been appointed a member of the Board of Health of Quincy.——Dr. A. F. Mahoney has been elected city physician of Chelsea, vice Dr. Frank H. Chase.

Hospital Notes.—The new Children's Hospital for Tuberculosis at Mattapan was dedicated January 29.——Fire in the Lawrence General Hospital, recently, placed the lives of seventy-five or more patients in peril, but was extinguished without casualties or panic, thanks to the cool-headedness of the nurses on duty.

Prenatal Clinic.—The first prenatal clinic, which was held at the Peter Bent Brigham Hospital, Boston, under the auspices of the Milk and Babies' Hygiene Association for prospective mothers has submitted an examination to be taken by those in the care of the clinic. A nurse will visit each of these patients every ten days to be sure the instructions have been carried out; after the birth of the child, the nurses will make daily visits for ten days.

MICHIGAN

Personal.—Dr. Arthur W. Skidmore, Three Rivers, has been elected head of the city Board of Trained Nurses.——Dr. Walter A. Briegel, city health officer of Tecumseh, is ill at his home with scarlet fever.

Small-Pox in Lapeer County.—Dr. W. H. Smith, of St. Clair, after an investigation of the small-pox situation in Lapeer County, reports to the secretary of the State Board of Health that he found two hundred cases and that many of them had been concealed and not previously reported to the health authorities.

MINNESOTA

Adopts Elective System.—To a limited extent the elective system has been adopted in the medical department of the University or Minnesota, Minneapolis.

Personal.—Dr. Joseph Nicholson, physician-in-charge of the Northwestern General Hospital, Brainerd, has been asked to establish and take charge of a hospital at El Basan, Albania.——Dr. W. O. Henry Paul, Owatonna, has been appointed superintendent of the sanatorium conducted in connection with the Immanuel Hospital, Mankato.

Would Consolidate Examining Boards.—The chairman of the committee in charge of the investigation of state functions having to do with public health, safety and agriculture, has proposed to the executive committee of the state economy and efficiency commission, a plan to consolidate the various examining boards under one bureau. At the head of this bureau is to be a director, under whom will be three commissioners, one of whom will have control of the various boards of medical, dental and pharmaceutical licensure, vital statistics study and control of epidemics, bacteriologic researches, Pasteur institutes, etc.; the second will have charge of the inspection of food for hotels and institutions; and the third will be in charge of public safety, fire prevention and similar work.

MISSOURI

State Board Meeting.—The State Board of Health met in St. Louis February 9 to 12 to examine applicants for license to practice and to hear charges against several physicians.

Physicians Must Not Advertise in Newspapers.—At a meeting of the Livingston County Medical Society at Chillicothe, February 5, a resolution was adopted that the physicians withdraw their professional care from the local newspapers, and that they do not allow their names to be mentioned in newspapers in connection with accidents or other matters of professional attendance.

New Officers.—Holt County Medical Society, at Oregon, January 8: president, Dr. O. W. Nauman, Craig; secretary, Dr. Walter S. Wood, Oregon.——Saline County Medical

Society, at Marshall, January 13: president, Dr. Floyd W. Tuttle, Mt. Leonard; secretary-treasurer, Dr. George A. Aiken, Malta Bend.——Cooper County Medical Society, at Boonville, January 6: president, Dr. Porter Williams, Tipton; secretary, Dr. C. S. Roberts, Boonville.——Linn County Medical Society, at Brookfield: president, Dr. Charles E. Jenkins, Brookfield; secretary, Dr. Foster W. Burke, Laclede.——Harrison County Medical Society, at Bethany: secretary, Dr. Cushman H. Vandivert, Bethany.——Ray County Medical Society, at Richmond: president, Dr. Robert Sevier; secretary, Dr. James E. Ball, both of Richmond.——Polk County Medical Society, at Morrisville: president, Dr. R. Lee Russell, Himansville; secretary, Dr. J. F. Roberts, Bollivar (reelected).——Greene County Medical Society, at Springfield: president, Dr. George B. Lemmon; secretary, Dr. Thomas O. Klingner.——Johnson County Medical Society, at Warrensburg: president, Dr. Henry Park, Knobnoster; secretary-treasurer, Dr. Oscar B. Hall, Warrensburg.——Clinton County Medical Society, at Lathrop: president, Dr. John F. Kimsey; secretary, Dr. F. H. Fulton, Plattsburg.

St. Louis

Sanitary Bill Boards.—After eight years of legal and verbal warring the bill board companies have surrendered and will comply with the law. As constructed at present, the bill boards are a menace to property in case of fire, afford a refuge for criminals and attract insanitary and unhygienic deposits.

No Laundry Bundles in Food Shops.—Butcher shops, restaurants, groceries and other food dispensing shops will not be permitted in the future to act as agents for laundries. The Health Department has ordered the laundry companies to discontinue agencies in food shops on account of the danger of spreading diseases through handling laundry bundles in these shops. The laundry companies readily acquiesced with the order.

Sanitary Inspection.—On request of Postmaster Selph the United States Public Health Service has detailed Dr. M. J. White to examine the sanitary condition of the postoffice buildings. This is the first instance where the postoffice buildings have received sanitary inspection. The examination will be made monthly. Medical inspection of employees will probably become a routine procedure in addition to the inspection of the buildings.

Nine-Hour Day for Nurses.—The state factory inspector has notified the hospital board that women employees of the city hospitals must not work more than nine hours a day, as required by the state law. The women nurses and other women employees have been working twelve hours. The change will require the employment of approximately one-third more nurses and an increase of the hospital budget of about $8,000 annually.

MONTANA

Addition to Hospital.—The addition to St. Joseph's Hospital, Lewistown, erected at a cost of about $40,000, was opened last month.

Health Officers of State Meet.—The first annual meeting of the eastern division of the Montana Health Officers' Association was held at Billings, January 30. Dr. Mott. H. Arnold, Billings, was elected secretary of the organization.

Seek Eugenic Law.—At a meeting of the Gallatin County Medical Association at Bozeman, January 24, a campaign to obtain eugenic marriage laws for the state was begun. Copies of the Wisconsin eugenic law were discussed, and members of the state and county bar associations took up various phases of the subject.

Personal.—Dr. John M. Scanland, Helena, has been reappointed superintendent of the State Hospital for Insane, Warm Springs, vice Dr. Arthur C. Knight, Butte, resigned.——Dr. A. P. Van Kirk, who recently resigned from government service at Old Fort Belknap, has entered practice at Lamont, Wash. and has been appointed local surgeon of the Spokane, Portland and Seattle Railway.——Dr. Sanford H. McCall, Missoula, has been elected president of the Missoula County Medical Society.

NEBRASKA

Hospital Notes.—A movement has been inaugurated for the erection of a negro hospital in Omaha.——An addition is to be built this spring to the Swedish Mission Hospital, Omaha, to cost from $60,000 to $70,000.——A new building is to be erected at the State Tuberculosis Sanatorium, Kearney, this year, at a cost of $40,000. The new building will be used exclusively for hospital purposes, while the old building now in use will be occupied as offices and living rooms for the superintendent and assistants.

Personal.—Dr. George P. Shidler has resigned as city physician of York, it is reported, on account of failure to receive the support of the mayor regarding an order for compulsory vaccination in the schools. Small-pox is reported to have occurred among the pupils of a business college. An order for the vaccination of all the students was disregarded by the head of the school, and in this he was supported by the mayor.——Dr. Robert C. Knode, Gering, has been appointed local surgeon of the Union Pacific System.

New Officers.—Franklin County Medical Association at Upland, February 3: president, Dr. William F. Dugan, Campbell; secretary-treasurer, Dr. Hal C. Smith, Franklin.——Elkhorn Valley Medical Association at Fremont, January 20: president, Dr. Frank Jensen, Newman Grove; secretary, Dr. Harry L. Wells, West Point. The association will hold its July meeting at Norfolk.——Lincoln Physicians' Research Club: president, Dr. Richard H. Spradling; secretary-treasurer, Dr. F. B. Dwiggins.——Colored physicians, pharmacists and dentists of Omaha organized an association January 21. Dr. August G. Edwards was elected president, and J. Merchant, Ph.G., secretary.——York County Medical Society at York: president, Dr. Edwin B. Hanna; secretary-treasurer, Dr. Edmund G. Zimmerer, both of York.——Dawes County Medical Society at Chadron, January 14: president, Dr. Andrew V. Stephenson, Crawford; secretary-treasurer, Dr. George W. Deemer, Chadron.

NEW YORK

New Officers.—Fulton Academy of Medicine, February 5: president, Dr. Herman W. Schlappi; secretary-treasurer, Dr. Everett A. Gladman.

Impostor Sought.—Health Commissioner Francis E. Fronczac, Buffalo, reports that a woman has been making a house-to-house canvas of the city, representing herself as being connected with the health department, and attempting to sell a medical book.

Personal.—Dr. Henry L. K. Shaw, Albany, has been appointed director of the department of child hygiene of the State Department of Health.——Dr. William Behan has been elected superintendent of the Mountain Sanitarium of the County of Broome.

Demand for Rural Hygiene.—The members of the New York State Grange at a recent convention, when told that the death-rate in the state in cities and towns below 8,000 was 15.4 per thousand, as against 13.7 in the larger cities, demanded a division of rural hygiene in the organization of the State Board of Health.

Matteawan Overcrowded.—At present there are 850 inmates in the State Hospital for the Criminal Insane, Matteawan, more than ever before at any one time. The superintendent states that this overcrowding is largely due to the fact that New York County has been dumping insane criminals into his institution, and he says that he will refuse to accept any more of these insane criminals from New York County.

New York City

Annex for St. Mark's Hospital.—At a dinner recently given to Benjamin T. Tilton, chief surgeon of St. Mark's Hospital, it was announced that a $150,000 annex was to be added to the hospital.

Honor State Health Commissioner.—Dr. Hermann M. Biggs, State Commissioner of Health, was the guest of two hundred physicians at a dinner at the Biltmore, February 7, at which Dr. George David Stewart presided as toastmaster.

Harvey Society Lecture.—The next lecture in the present course of Harvey Society lectures will be given February 28. Prof. Richard P. Strong, Harvard University, will lecture on "The Etiology of Oroya Fever and Verruga Peruviana."

Women as Hospital Interns.—The Commissioner of Charities has under consideration the question of appointing women as interns at the Metropolitan Hospital. At present these positions are open to men only, but it is felt that as a year's hospital training is soon to be required of every graduate in medicine before a license to practice medicine is issued, that this opportunity for training should be open to women now entering the profession.

Hospital Annex Dedicated.—The new hospital in connection with the work of the Hebrew Infant Asylum at Kingsbridge Road and University Avenue, the Bronx, was dedicated February 8, at the nineteenth annual meeting of the asylum.

The building cost $25,000 and here each infant will be kept in a single room for three weeks under careful observation until the physicians decide that the child is at least free from the evidences of disease and may safely be transferred to the wards.

To Facilitate Early Diagnosis of Diphtheria.—Despite the fact that there are a number of collecting stations in the city where throat culture for the diagnosis of diphtheria may be left, and that these specimens are collected every evening and reported on by telephone before 10 o'clock the following morning, the Department of Health feels that time might be gained, and has under consideration a plan for the installation of incubators at some of the collecting stations, particularly those that are open all night.

Operations on Adenoids and Tonsils.—The Public Health Hospital Budget Committee of the New York Academy of Medicine has adopted resolutions recommending that all operations on tonsils should be performed in a hospital or in such dispensaries as have operating rooms and recovery wards; that private hospitals of the city be requested to cooperate with the health department in the care of children with enlarged tonsils; that the hospitals be provided with adequate facilities for such cases; that the city compensate private hospitals for such service, and that the public hospitals be requested to undertake such cases without compensation.

Health Department Warns Against "Cure-Alls."—Dr. Sigismund S. Goldwater, the new health commissioner, has issued a bulletin cautioning the public against putting too much faith in radium as a cure for cancer. The warning was issued for the purpose of protecting the public against fakers who may trade on the public's credulity. At the same time Dr. Goldwater said that the Board of Health had refused the request of Dr. Hans Karfunkel, a Berlin physician, who has asked permission to try a modified Friedmann tuberculosis serum in this city. The present board of health stands by the former board which adopted the resolution that no serum containing living bacilli should be employed in the treatment of tuberculosis patients without the board's permission.

Central Council of Public Health.—At the meeting of the Public Health Federation of the City of New York, Dr. John H. Huddleston officiated as chairman and was elected head of the Central Council of Public Health. The general aims of the Council were set forth as follows: To provide for conferences of private health organizations. To act as a clearing house for the exchange of ideas and information in reference to the public health of the city. To coordinate and prevent duplication of the various public health activities of the city. To promote cooperation in the investigation and study of health problems. To study the city budget in its relation to public health. To take an active interest in the administration of all such branches of the city government as have a direct bearing on public health.

Lack of Efficiency Charged in Dealing with Typhoid.—The Bureau of Municipal Research which has completed an investigation of the methods employed in handling the typhoid fever epidemics in this city in 1911 when there were 1,133 cases, and in 1913 when there were 948 cases, charges that there was lack of efficiency in dealing with these epidemics. It is stated that the experience of 1911 left no excuse for failure to handle the situation in 1913. The report points out twenty-eight defects in the method employed in 1913. Some of these defects were delay in reporting cases and lack of effort to secure the cooperation of other city departments in improving the notification of typhoid fever cases. Inspection and action on inspection was too long delayed; inspector's reports were inaccurate and incomplete and lacked in uniformity; cases had not been taken seriously enough when only 20 or 30 per week were reported, and typhoid vaccine had not been explained to the public. It is claimed that had telephones been used, and had inspection and action on it been prompt, many cases of typhoid would have been prevented. The belief was expressed that at a conservative estimate $100,000 a year should easily have been saved in wage loss and doctor's and funeral bills due to preventable typhoid.

NORTH CAROLINA

Summer Camp Site.—The War Department has purchased a large tract of land, east of Asheville, where it will establish a summer camp for state troops and the national guards of various adjacent states.

To Erect and Endow Hospital.—Dr. John W. Long, Greensboro, has provided a fund to be placed in the hands of the Foreign Mission Board of the Methodist Episcopal Church in South Africa, to erect and maintain a hospital for the treatment of special diseases incident to South Africa, at some advantageous point in that country. The hospital is a memorial to his daughter, Miss Mary Long.

Personal.—Dr. Francis J. Clemenger, Asheville, sailed for London, January 31.——Dr. W. Herbert Wootten, Davidson, was shot by a druggist, February 9, while making a professional call at the home of the latter.——The officers of Drs. Charles L. Summers, Roscoe L. Wall, Albert D. Edwards, Van McK. Long, and Dr. Wingate M. Johnson, Winston-Salem, were destroyed by fire in the O'Hanlon Building.

Hookworm Education.—The report of Dr. C. L. Pridgeon, assistant secretary of the State Board of Health for the Eradication of Hookworm Disease, for the year 1913 shows the interesting fact that of the one hundred counties of the state, ninety-nine have made supplementary appropriations to aid in the work being done by the Rockefeller Foundation and the State Board of Health. Several of the counties which were surveyed two years ago have made appropriations for a second canvass. Prior to 1913 there were 217,033 people examined in the state for hookworm, and 88,119 were found infected and treated, or 40 per cent. During 1913, 107,887 people were examined, and 23,533 were found infected, or 21.8 per cent., showing the value of the previous educational work. In addition, the work of private physicians, as reported to the State Board of Health regarding hookworm, shows that prior to 1913 they had treated 40,568, and in 1913 they treated 11,905 cases, making a total treated by private practitioners of 52,473 cases, which, added to the above, shows that North Carolina in the past few years, as shown by the records in the State Board of Health office, there have been treated for hookworm, 164,145 patients. In addition to making examinations of one-seventh of the state's population, the hookworm staff of the state board have distributed nearly one million pieces of literature relating to hookworm, sanitation and kindred topics, besides delivering 1,089 public lectures, listened to by upward of 100,000 citizens. This does not include the hundreds of other daily lectures given during the period mentioned by the field demonstrators in making the clinical examinations. The work for 1914 will be prosecuted with increased vigor.

NORTH DAKOTA

Small-Pox Near Canadian Line.—Small-pox in several of the northern counties of the state, although looked after carefully by the State Board of Health, with proper quarantine, the enforcement of vaccination, etc., has induced the Canadian authorities to quarantine against St. John, near the northern border. The Great Northern railroad has been restrained from selling tickets for points north, and train crews have been compelled to change at Rolla instead of at St. John. The disease is well under control and the boundary quarantine will soon be raised.

PENNSYLVANIA

Personal.—Dr. Edwin A. Curry, Danville, suffered a cerebral hemorrhage several weeks ago.——Dr. Watson Marshall has been appointed demonstrator of laryngology in the University of Pittsburgh.

Biologic Research Society Holds Open Meeting.—The Society for Biological Research of the University of Pittsburgh held its first open meeting January 29, when Dr. Ross G. Harrison, of Yale University, delivered an address on "The Life of Tissues Outside the Organism."

New Dispensary.—A free medical dispensary has been installed in the rooms of the New Convent Mission, at Reed, Crawford and Pride Streets, Pittsburgh. Dr. Frederick V. H. Wooldridge is physician in charge, and Dr. Alexander M. Stevenson is in charge of the nose and throat department.

Norristown to Limit Admission of Patients.—The trustees of the Norristown State Hospital for the Insane have adopted resolutions so that all the counties of the southeastern district may be entitled to a "ratable and equitable privilege." The maximum limit of patients to be received will be 1,500 in the male department and 1,550 in the female department. With every commitment must be presented a certificate signed by the chief resident physician of the respective department and by a member of the board of trustees from the county whence the patient is sent, and of another member of the board of trustees from some other county, approving that application or the admission of the patient to the hospital, otherwise the officers of the institution are instructed to refuse to admit the patients.

Winter Cholera at Grove City.—It is reported that 50 per cent. of the 4,000 people in Grove City have been affected with a disease spoken of as "winter cholera." Business and industrial plants have suffered on account of illness among their employees, but no deaths have occurred. The disease is under investigation by the state health commissioner and his assistants, who reported, February 8, that it had succeeded in checking the outbreak of cholera at Grove City. The engineer sent to that town found the trouble due to the fact that air pressure was used in forcing water out of the wells, from which the municipality derived its water supply. The water was treated with copperas, on February 7. The report of the day before showed that 110 new cases developed. February 7 there were 57 new cases, and February 8, only 12.

Philadelphia

Hospital Site Purchased.—Archbishop Prendergast has acquired a tract of land of 11 acres in West Philadelphia, on which it is proposed to establish a large hospital. The site is valued at $200,000.

Weir Mitchell Lecture.—The Weir Mitchell Lecture will be delivered February 5, at 8:30, by Dr. Harvey Cushing of Harvard University, on "Clinical Types of Dyspituitarism," at the College of Physicians and Surgeons, Twenty-Second and Chestnut Streets.

Hospital's Income Increased.—On February 11, Judge Staake granted a petition to permit the Jeanes Hospital, the benefaction of the late Annie T. Jeanes, to receive a quarter of a million dollars annually as an income, and also granted permission for a property value of five million dollars, to be held by that institution.

Child Federation's Campaign.—A meeting was held at the Pennsylvania Hospital, February 10, of the Pennsylvania Association of Hospital Social Workers, and plans for increasing the efficiency of these workers connected with certain city hospitals were discussed. The following officers were elected for the ensuing year: president, Mrs. Blanche Jobes, Orthopedic Hospital; vice-president, Miss Mary E. Pollock, Jefferson Hospital; and secretary and treasurer, Miss Agnes Jacobs, Henry Phipps Institute.

Clergymen Join Housing Crusade.—After an inspection of the courts and alleys running back of South, Lombard, Bainbridge, Carpenter, Marshall and Fitzwater Streets, conducted by Bernard J. Newman, secretary of the Philadelphia Housing Commission, the ten ministers of various denominations, pledged their cooperation in the work of the commission, which desires that a comprehensive survey be made; that landlords and lessees be forced to purge the properties of uncleanliness and that stricter provisions be made for observation of the law.

VIRGINIA

Plead for Tax Exemption.—A committee of physicians appeared before the House Committee on Finance to ask that the statute requiring a license tax from physicians be repealed. The committee states that physicians are now taxed from $10 to $25 for licenses, the aggregate amounting to $44,000 a year, and that only four other states of the Union, North Carolina, Delaware, Louisiana, and Georgia, require the tax.

Health Specialists to Meet.—For the first time in its history the Virginia Public Health Association is to hold its meeting separately from the Medical Society of Virginia. The meeting will be held at Charlottesville, April 23 and 24, under the presidency of Dr. Moseby G. Perrow, Lynchburg. Addresses will be delivered by Dr. Harvey W. Wiley, Dr. Carl Alsberg, Dr. William C. Woodward, Washington, D. C., and Dr. Ennion G. Williams, Richmond State Health Commission.

Personal.—Dr. Albert P. Traynham, Richmond, has been appointed district hookworm inspector by the Rockefeller Sanitary Commission, to succeed Dr. Knex E. Miller, who has resigned to enter the U. S. P. H. S.——Dr. J. Thomson Booth, Ashland, has been appointed district hookworm inspector, vice Dr. G. L. Koelmer, who has resigned to enter practice in Salem.——Dr. Hugh M. Taylor, Richmond, who was operated on in a hospital in Philadelphia for tic douloureux, is reported to be making good progress toward recovery.——Dr. Ernest C. Levy, chief health officer of Richmond, Ramon D. Garcin, and M. D. Hoge, Jr., have been appointed a committee to prepare the exhibit of the Richmond Board of Health in the Chamber of Commerce Building.

WISCONSIN

Tuberculosis Notes.—The forty-five inmates of the Blue Mound Sanatorium, Wauwautosa, were imperiled, February 10, by a fire which destroyed the institution, with a loss of $50,000. Fortunately no casualties occurred.——The State Board of Control has accepted recommendations for a tuberculosis camp on Tomahawk Lake.——Eau Claire County has a well-kept sanatorium, erected by the Eau Claire Anti-Tuberculosis Society. The institution is situated on the southern slope of Mt. Washington, west of the city, and accommodates twenty patients.

Personal.—Dr. and Mrs. Richard C. Buchanan, Green Bay, and Dr. and Mrs. James B. Lenfestey, De Pere, sailed for Europe, February 12.——Dr. Fay T. Clark, Waupun, has been appointed a member of the Wisconsin State Board of Medical Examiners, vice Dr. Milton, resigned.——Dr. M. J. White, assistant surgeon at the Soldiers' Home, Milwaukee, has resigned, and will take his former place on the medical staff of the Milwaukee County Hospital for the Insane, Wauwatosa.——Dr. Frank S. Wasielewski has been elected president, and Dr. Rudolf F. Teschan, secretary, of the board of trustees of the Johnston Emergency Hospital, Milwaukee. Dr. William F. Becker has been elected president and Dr. Oscar Lots, secretary, of the staff of the hospital.

GENERAL

Annual Meeting of the Federation of State Boards.—The annual meeting of the federation will be held at the Congress Hotel, Chicago, Wednesday, February 25, the day following the conference of the Council on Medical Education. The program includes, among others, the following addresses: "Uniform Curriculum for Medical Schools," by Dr. John L. Heffron, Dean of the College of Medicine of Syracuse University; "The United States Medical Services and Medical Education," by Lieut.-Col. J. R. Kean, Medical Corps, United States Army; "Standardizing Medical Education," by Dr. Harold C. Ernst, Professor of Bacteriology, Harvard University Medical School, Boston; "Instruction in Pharmacology and Therapeutics," by Dr. Samuel W. Lambert, Dean of Columbia University College of Physicians and Surgeons, New York City; Dr. Walter L. Bierring, President of the Iowa State Board of Health and Medical Examiners, Des Moines; Dr. Bernard Fantus, professor of pharmacology and therapeutics of the University of Illinois College of Medicine, Chicago. Other papers by prominent speakers will be given on medical practice acts, preliminary credentials, practical examinations and reciprocity.

Life Insurance Directors to Meet.—The fourth mid year meeting of the medical section of the American Life Convention will be held at French Lick, Ind., March 4 to 6, under the chairmanship of Dr. James H. Stowell, Chicago. The preliminary program, which has just appeared, shows an unusually interesting list of subjects for addresses and discussions.

Bequests and Donations.—The following bequests and donations have recently been announced:

Providence Hospital, St. Louis, $5,000 from the estate of Adolphus Busch.

Samaritan Hospital for the Aged, Society for the Relief of the Destitute Blind; New York Post-Graduate Medical College, each $1,000 by the will of Emily Chamberlain.

St. Vincent's Hospital, New York City, $3,000, by the will of Louisa Verret.

Vanderbilt Clinic, New York City, $2,700 donation by John A. Fordyce.

To build a hospital for the treatment of tuberculosis at Pendra Road, India, a donation of $5,000 by Mr. and Mrs. Durant Jones, Perry, Iowa.

Hospital Work of the Gould Alliance.—The annual report of the hospital service managers of the Missouri Pacific-Iron Mountain System shows an increase in the net surplus for the year of $12,163, of which $5,000 has been set aside for an emergency hospital at Argenta, Ark. During the year the Red Cross hospital car made an instruction tour of the entire system, giving lectures and demonstrations to the employees of the system. The hospital property of the system was turned over to the employees a year ago, and since that time additional hospital facilities have been secured at Busch and Illmo, Ill.; Nevada, Mo.; Concordia and Yates, La.; and Fort Smith and Newport, Ark.

FOREIGN

Discovery of Radium in the Caucasus.—Consul Snodgrass of Moscow reports that during geological investigations in the Caucasus recently radium and mesothorium have been discovered at the mineral springs near Sotobi and Sukhum

International Congress on Thalassotherapy.—This congress will convene at Cannes, on the Riviera, April 15, and will discuss all manner of subjects connected with the seashore, sunlight, sea-bathing, etc., as means of therapeusis. The main topic for discussion will be "Marine Heliotherapy," and a number of addresses are to made by leading authorities on the biologic aspect, dosage and therapeutic effects in various affections, especially pulmonary and surgical tuberculosis. The fee of $4 entitles one to the reports and transactions when published later. The treasurer is Dr. Gimbert, Villa des Myrtes, Cannes, France. The secretary is Dr. G. Baudouin, 21 Rue du Mont-Thabor, Paris, France.

Small-Pox in New Zealand.—A report from New Zealand under date of Jan. 7, 1914, describes an epidemic of small-pox in that country which affected two thousand people, chiefly Maori natives, who are very susceptible to the disease and who are not vaccinated. An epidemic prevailed at the same time in Australia, with 900 cases, but no deaths. The disease in the Maoris for the most part was mild. Many confluent cases were found though the percentage of deaths was small. On account of the character of these people and their wandering life accurate statistics could not be obtained. The disease was traced, it is said, to a case in a man from Utah, U. S. A., who had a pustular disease of a mild type while on the steamer going over.—(*Pub. Health Rep.*, Feb. 13, 1914.)

CANADA

Personals.—Dr. Edward A. Braithwaite, Edmonton, Alta., has been appointed to the Medical Council of Canada, in place of Dr. George A. Kennedy, Macleod, Alta., deceased.——Dr. Francis J. Shepherd, Montreal, has gone on a trip to Panama.——Dr. de Lotbiniere Howard, Montreal, is leaving for England and the Continent to spend the spring and summer in graduate work.——Dr. A. G. Morpy, Montreal, has sailed for the Mediterranean.

University News.—Sir William Macdonald, Montreal, has been elected chancellor of McGill University, in succession to the late Lord Strathcona. The new chancellor's donations to McGill total over $5,000,000, his special gift being the entire physics building completely furnished.——Dr. Mines, who has been loaned to the University of Toronto by the University of London, England, is doing special work in connection with physiological studies in the medical department.

New Officers.—Kent County (Ont.) Health Officers' Association: Dr. Charles H. Charteris, Chatham, president; Dr. Frederick L. Reid, Merlin, secretary.——Medical Association of the Counties of Stormont, Dundas, Glengarry, Prescott, and Russell, Ont., at Cornwall, February 12: President, Dr. Robert R. Reddick, Winchester; secretary-treasurer, Dr. William E. Crain, Crysler. The executive committee was instructed to frame a new tariff of fees for submission to the next meeting in Ottawa early in March.——Aesculapian Club, Toronto: President, Dr. Bruce L. Riordan; secretary, Dr. George Elliott, renominated.

Hospital News.—The Toronto Hebrew Hospital Association has been recently formed and collections are being made and donations solicited for a new Jewish hospital in Toronto.——The Coburg (Ontario) Hospital has received a check for $20,000 from the estate of a prominent citizen of Port Hope, Ont.——Mr. John C. Eaton, Toronto, has presented a modern motor ambulance to the Toronto General Hospital.——Strathroy, Ont., opened a fine new hospital February 9.——The Hamilton Health Association is asking the board of control to erect a new infirmary at a cost of $75,000.——Kamloops, B. C., is to grant $15,000 for a Royal Inland Hospital.——The King George Hospital for Infectious Diseases has been completed at Winnipeg, Man., at a cost of over $300,000.

LONDON LETTER

(From Our Regular Correspondent)

London, Jan. 31, 1914.

Memorials to Lord Lister

In the presence of a distinguished company which included Dr. Herringham, chancellor of the University of London, Sir Rickman Godlee, president of the Royal College of Surgeons and nephew of Lord Lister, Mr. and Mrs. J. J. Lister and Sir David Ferrier, Lord Rayleigh unveiled a mural tablet in the central hall of King's College which bore the following inscription: "In affectionate and respectful memory of Joseph Baron Lister, F.R.C.S., O.M., Professor of Clinical Surgery in King's College from 1877-1892, and for many years consulting surgeon to the King's College Hospital, member of the Council, and Life Governor of the College, this tablet is erected. His name will be handed down to posterity as the founder of antiseptic surgery, one of the greatest discoveries in history, and a source of inestimable benefit to mankind." Addressing the assembly, Lord Rayleigh said that Lister was one of the great men of his generation. One hardly knew whether to be more impressed by the importance of his achievements or by the modesty with which he seemed to regard them. If any man could properly be satisfied with his life's work it was Lister; but he did not seem satisfied. At a dinner given to celebrate the institution of the Order of Merit (an order instituted by the late King Edward for eminence in science and literature), Lister spoke of his work wtih a touch of melancholy as having been done a long while ago and as if he had hoped to do yet more.

At Edinburgh, where Lister did so much of the work of initiating the antiseptic system, arrangements have been nearly completed for the establishment of a memorial to be known as the Lister Institute. It will be devoted mainly to research in bacteriology and pathology. The work will be performed in connection with the university, but the institute will be managed by an independent board consisting of representatives of the Royal Colleges of Physicians and Surgeons, the University and probably the Carnegie trustees. Certain facilities for teaching will also be provided.

Life in an Igloo

At the Royal Society of Medicine, Surgeon G. M. Levick, R.N., lectured to a crowded audience on "The Experiences of Captain Scott's Northern Party from a Medical Point of View." He described how he and five comrades spent a winter in an ice-cave, or igloo, of their own digging, on the shores of Robinson's Bay, the ship which was to have taken them north having become frozen in. The party hit on the idea of burrowing below ground because, with a perpetual hurricane blowing, life above ground was intolerable. The cave undoubtedly saved their lives. It was hewn out of the clear blue ice and took a long time to make, but it was an adequate protection and less uncomfortable and unhealthy than might be supposed. The members of the party had only six weeks' provisions and realized that they should have to live on seal-meat during the greater part of the seven months in front of them. They were lucky in getting a number of seals, which are scarce during the winter, and also about ninety old penguins, which were molting, and had consequently delayed their migration. The penguins had not an ounce of fat on them, but they afforded a pleasant variety of diet. The party lived exclusively on seal-meat for a while, until they managed to get used to blubber. The blubber helped them to forget their great craving for sugary foods, but every now and then they revolted against it and could not touch it. They had great difficulty in cutting the seal-meat, as it was as hard as iron. They broke one of their axes on it and eventually had to fall back on a geologist's chisel and hammer. They used an old biscuit-tin as a stove and dripped blubber into it. It took the cook the whole day to prepare the evening meal. They scarcely dared to go out at all; every time they did go out they got frost-bitten. Ventilation troubled them a good deal until they drilled a chimney. One morning, after a blizzard, they found that none of their lamps would burn. They tried to light a "Primus" stove, and then a match, but these went out immediately. Apparently there was almost no oxygen left in the air. As soon as they dug a hole through the drifted snow the lamps flamed up. The curious thing was that the members of the party experienced no discomfort. In a warmer climate they would probably have died. Another remarkable fact was that none of them suffered from scurvy. The fact that they were all comparatively fit at the end of their imprisonment was a wonderful testimony of the value of a flesh diet. Their first meal after their escape was simply enormous. They ate fourteen biscuits and 2 pounds of pemmican and oatmeal each, besides lard, butter and chocolates. One of the party could not lift his legs to get into bed. Yet none of the members of the party had indigestion.

The Census of the Insane

The eleventh volume of the census of England and Wales for 1911, which deals with infirmities, has just been issued. The total number of the insane in the country is 161,993; 76,243 males and 85,750 females, representing a proportion of 4,491 per million. This is a considerable increase over the census of 1901, when the proportion was 4,078 per million, but the increase in the number of insane is no proof of the growth of insanity in the community. There is really not sufficient evidence for a correct judgment to be formed. The care to segregate persons suffering from milder forms of insanity is probably the reason for the apparently excessive increase in the numbers during the last forty years. Of the 161,993 persons who were returned as suffering from mental infirmity, 106,660 were returned as lunatic, 25,405 as imbecile, and 29,928 as feeble-minded. In 1901, 83,772 were returned as lunatic, and 48,882 as imbecile or feeble-minded. Thus there is an increase of 22.1 per cent. in the insane taken as a whole, of 27.3 per cent. in the lunatic, and of 13.2 per cent. in the imbecile or feeble-minded. The largest percentage increase in the insanity-rate occurs in the case of children under 15. The total increase is 30.8 per cent., the rate for lunatics being 42.3, and the rate for imbeciles or feeble-minded being 30.3.

The Census of the Deaf and Blind

The volume of the census of England and Wales of 1911 which deals with infirmities has just been issued. For the first time an attempt has been made to obtain information regarding the deaf other than deaf mutes. In view of the worthlessness of returns of the partially deaf, it was decided to reduce the inquiry to its lowest terms and to ask only whether there was total deafness. A similar difficulty in regard to blindness was dealt with in the same way. In the case of the blind it is probable that a number of persons who possess some degree of sight have been returned as totally blind. The reason for this is that a defect of vision which forbids the ordinary means of earning a livelihood has been considered as important as total blindness. The numbers returned totally blind were 26,336, of whom 13,257 were males and 13,079 females—that is, one person out of every 1.370 is blind, one out of 1,316 males and one out of 1,424 females. These numbers compare favorably with the last census, taken in 1901, when there were 25.317 blind people, or one out of 1,285. There has, indeed, been a steady improvement at each census since 1851, when one person out of every 979 was returned as blind. The totally deaf number 26.649, of whom 10,640 are males and 16,009 females. In addition there are 13,427 who also are dumb, and 1,695 who are stated to be dumb but not stated to be deaf. Of the two latter groups 8.167 are males and 6,955 females. The greatest proportion of the deaf and dumb, both male and female, are aged from 55 to 65 years. The proportion for all ages is lower than at any census since 1851, and the improvement, as might be expected from the trend of modern educational methods, is much more marked in early than in later life. The largest number of deaf and dumb males are employed as boot and shoe makers, the smallest as bricklayers' laborers. Of the females, dressmakers form the greatest proportion.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Jan. 31, 1914.

Personal

The well-known pediatrician, Prof. A. Baginsky, has been chosen an honorary member of the Verein für innere Medizin und Kinderheilkunde.

January 30, Professor Neumann of Königsberg, the distinguished pathologic anatomist, celebrated his eightieth birthday.

January 27, Professor Grabower of Berlin, known particularly on account of his work on the innervation of the larynx, died at the age of 64.

Privy Councillor Volmer, for many years the director of the department of internal medicine of the Catholic hospital in Berlin, died January 29.

Kaiser Wilhelm Institute for the Physiology of Work

The erection of an institute originated by Professor Rubner of Berlin, to be devoted to the physiology of work, has been begun under the auspices of the Kaiser Wilhelm Society for the Advancement of Science. The building will be placed next to the University Institute for Physiology on Invaliden-Platz. Professor Rubner has been appointed director of the institution. He will have three assistants, one for physiologic chemistry and metabolic work, one for experimental physiology and psychology, and one for statistical and economic studies.

The purpose of the institution is to obtain exact data regarding human effort of a physical and intellectual nature, both in general and with reference to the special conditions in childhood, youth and old age, and in various constitutions and races. Studies are to be inaugurated to determine the influence of the air temperature, radiant heat, and the moisture and the movement of the air on work. With reference to nutrition, a study will be made of the distribution of vegetable and animal diets, and the peculiarities of nutrition in various districts of the country, the relations of diet in the country and the city, the nutrition of families with few and those with many children. The investigation of the hygiene of the trades will constitute an important aim and it is hoped in this way to lay the foundation for an extension of the principles underlying prophylactic measures against the various influences unfavorable to health.

From this outline it may be seen how high an aim the new institution is to achieve. The extensive experience of the director, Professor Rubner, justifies the expectation that in a short time a series of important facts will be discovered in the institute.

Rise of Life Expectancy in Prussia

Official statistics recently published indicate that the average length of life in Prussia is steadily rising. This satisfactory condition must be regarded as the result of improvement in living conditions of the population, the extraordinary advance in sanitation, the care of the drinking water, attention to drainage, and finally, improvements in the treatment of the sick. While the average life expectancy of infants in the period from 1867 to 1876 was 33.05 years for boys and 35.74 for girls, it had risen for the period from 1906 to 1910 to 46.42 and 50.03, respectively. At the twentieth year of life, the increase in the average length of life is 5.18 and 5.75 years, respectively, while at fifty it is 2.33 and 2.59.

German Roman Catholic Bishops on Sex Education

The question whether children shall be instructed in sex hygiene, forms a matter of dispute between those who see in such instruction an occasion of injury to the morals of the young and those who hold it very important to impart biologic facts, even to children of school age. The problem is of interest to physicians, inasmuch as the latter party demand that the explanation of these matters to children shall be made a part of the duties of the school physician. Hence it is of interest to learn the conclusions which the Roman Catholic bishops of Germany reached on this subject at their conference held in 1913. The assumption that in accordance with the pronounced conservative tendency, these clergymen would be opposed to any form of instruction in sexual matters is not justified by their resolutions. The resolutions are as follows:

In general, the instruction of youth in sexual matters should be treated with the greatest caution and reserve. In individual cases, where it is necessary, it is the function of the parents, the religious teacher, the father confessor, or the teacher. Sexual instruction in common by lectures to groups of pupils or graduates is to be condemned. The young should be trained early in modesty and if there is need of instruction in sex matters after leaving school, it should be imparted to girls by the mother, to boys by the mother or the father, or in both cases by the father confessor with the greatest caution, teaching and warning in private. Gymnastic institutions or exhibitions for boys and girls together should never be approved. Also all public exhibitions or gymnastics for girls or women, and still more, public swimming matches and the swimming of boys and girls together should be emphatically condemned. Physical exercise for girls in a manner suited to the capacity of the female body and to the tender feeling of childhood and youth is not to be condemned. But to determine the extent of this (and in individual cases, the limited admission of spectators) is the business of the educator with religious sensibility and not exclusively of a technical expert. It would be much to be regretted if the attention to physical exercise on the part of the female sex should be carried to such an extent as to lead to inattention to the heart life, an underestimate of the spiritual and emotional training, a weakening of womanly modesty and lessening of the love for quiet domestic activities. It is a matter of most serious complaint that feminine dress both for children and adults in wide circles at the present time has become shameless, and the conference would gladly hail a determination on the part of the Catholic Women's League to wage a bold, decided and persevering warfare along the whole line against that disgraceful perversity. It would be much to be deplored if parents should be so short-sighted as to disregard this earnest appeal from their religious leaders.

From a medical standpoint, one will be able to agree with some important points in these resolutions, although not with all.

Deaths

Roswell Park, M.D., eminent as a surgeon, scientist and teacher, died suddenly at his home in Buffalo, February 15, from heart disease, from which he had suffered for several months.

He was born in Pomfret, Conn., May 4, 1852, the son of Rev. Roswell and Mary Brewster Baldwin Park. He was graduated from Racine (Wis.) College with the degree of A.B. in 1872, receiving his A.M. degree three years later. His medical course was taken at Northwestern University Medical School, from which he graduated in the class of 1876.

He began his work as a teacher in the year after his graduation, when he was made demonstrator of anatomy in the Women's Medical College of Chicago. After two years he became adjunct professor of anatomy in his alma mater, resigning this position in 1882 to become a lecturer on surgery in Rush Medical College. A year later he was appointed professor of surgery in the medical department of the University of Buffalo, and held this position until the time of his death.

He was a prolific contributor to the literature of surgery and pathology. He was the author of a Text-Book of American Surgery, published in 1896, of an Epitome of the History of Medicine, which appeared a year later, and of the Principles and Practice of Modern Surgery, which was brought out in 1907. In 1891, he delivered the Mütter Lectures on Surgical Pathology.

Dr. Park served his state as major and surgeon of the Fourth Brigade, N. G., S. N. Y. He was consulting surgeon at Fort Porter, Buffalo, under special contract with the Surgeon-General of the Army in 1899, and was one of the first to be commissioned as a first lieutenant, Medical Reserve Corps, U. S. Army, on the formation of the corps in 1907.

Dr. Park was deservedly the recipient of many honors. Lake Forest University conferred on him the honorary degree of M.D. in 1892; Harvard University, that of A.M., in 1895; and Yale University, that of LL.D., in 1902. He was appointed director of the New York State Cancer Laboratory in 1901. Of late years he had taken a great interest in the research work regarding cancer, and his opinion was regarded as authoritative. He was an anatomist of unusual erudition; a pathologist of the highest rank; a surgeon of great clinical skill and rare judgment; a teacher who possessed the somewhat rare faculty of making his students remember what he taught them. While a man of pronounced opinions, he was greatly beloved by his fellow practitioners, to whom he endeared himself by unfailing courtesy, and by giving without stint of his stores of knowledge.

Roswell Park, 1852-1914

Nathan S. Marshall, M.D. Jefferson Medical College, 1858; formerly of Illinois and secretary of the Centennial Medical Society, Olney, Ill.; one of the survivors of Commodore Peary's expedition to Japan in 1852; died at the home of his daughter in Knoxville, Tenn., February 7, aged 81.

Henry Laird Todd, M.D. University of Maryland, Baltimore, 1851; county commissioner of Wicomico County in 1867, and county treasurer in 1901; died at his home in Salisbury, January 23, from acute gastritis, aged 83.

Margaret A. Osborn (license, Indiana, 1897); for fifty-three years a practitioner of medicine of South Bend; died at her home, January 29, aged 86.

George Lloyd Magruder, M.D. Georgetown University, Washington, D. C., 1870; emeritus professor of materia medica and therapeutics and formerly dean of the faculty of his alma mater; a Fellow of the American Medical Association; one of the originators of the Central Dispensary and Emergency Hospital, Washington; a member of the consulting board of Providence Hospital, and of the board of directors of the Government Hospital for the Insane; prominently identified with the campaign for pasteurized milk in Washington, and other civic improvements; died at his home, January 28, from heart disease, aged 65.

Edward Payson Fowler, M.D. New York Medical College, New York City, 1855; a Fellow of the American Medical Association and New York Academy of Medicine; formerly president of the New York Medico-Chirurgical Society; author of several books on neurologic subjects; at one time visiting physician at Ward's Island; died at his home in Pelham Manor, January 29, from pneumonia, aged 79.

Warren S. Williams, M.D. Western Reserve University, Cleveland, Ohio, 1884; a Fellow of the American Medical Association, and the third of his family in direct line to practice medicine in Kendallville, Ind.; died at his home, January 25, aged 52.

William Wistar Wilson, M.D. Medical College of the State of South Carolina, Charleston, 1879; a member of the South Carolina Medical Association; died at his home in Williamston, January 29, aged 63.

John H. Wood, M.D. Tulane University, New Orleans, 1891; formerly a Fellow of the American Medical Association; died at his home in Hubbard, Texas, January 21, from cerebral hemorrhage, aged 47.

Charles E. Froelich, M.D. University of Copenhagen, Denmark, 1870; a member of the Connecticut State Medical Society; died at his home in Hartford, January 31, from acute gastritis, aged 68.

William Pearson, M.D. Vanderbilt University, Nashville, Tenn., 1888; of Joshua, Texas; died in a sanitarium in Fort Worth, Texas, January 28, from cerebral hemorrhage, aged 56.

William Clark Brittain, M.D. Eclectic Medical Institute, Cincinnati, 1873; a Fellow of the American Medical Association; died at his home in Cochranton, Pa., January 30; aged 64.

Caroline Helen Van Horne, M.D. Women's Medical College of Pennsylvania, Philadelphia, 1894; a member of the medical staff of the Englewood (N. J.) Hospital, and physician to the Day Nursery; a member of the Medical Society of the State of Pennsylvania; died at her home in Englewood, February 3, from heart disease, aged 51.

George Fleet Dudley, M.D. Washington University, St. Louis, 1863; one of the founders and first president of the St. Louis Medical Society, and first health commissioner of St. Louis; for two terms coroner of St. Louis County; a surgeon in the Confederate service during the Civil War; died at his home February 2, aged 79.

Ray Vaughan Pierce, M.D. Eclectic Medical Institute, Cincinnati, 1865; of Buffalo, N. Y.; of Pierce Golden Medical Discovery and other patent-medicine fame; died at his winter home on St. Vincent's Island, Fla., February 3, from cerebral hemorrhage, aged 64.

Eugene D. Collett, M.D. Sioux City (Iowa) College of Medicine, 1909; formerly of Mangum, Okla., died in North Platte, Neb., Dec. 29, 1913.

William Kelly Simpson, M.D. College of Physicians and Surgeons, 1880; a Fellow of the American Medical Association, and New York Academy of Medicine; a member of the American Laryngological Society; for nine years professor of laryngology in his alma mater; consulting laryngologist to the Seton and St. John's hospitals, Yonkers, and the Somerset (N. J.) Hospital; laryngologist to the Vanderbilt Clinic, and consulting otologist to the Presbyterian Hospital, New York City; died at his home in New York City, February 6, from cerebral hemorrhage, aged 58.

Daniel C. Logue, M.D. New York University, New York City, 1856; acting assistant surgeon, U. S. N., during the Civil War, and surgeon of the *Monitor* during the historic fight with the *Merrimac*; after the war a practitioner of Brooklyn until 1900, when he retired from practice and moved to Bellmore, L. I.; died at his home, February 4, aged 81.

James Harvie Dew, M.D. University of Virginia, Charlottesville, 1867; a Fellow of the American Medical Association and the New York Academy of Medicine; a Confederate veteran; for nine years professor of anatomy, physiology and hygiene in the New York high schools; died at his home in New York City, January 26, aged 70.

George Douglass Dickerson, M.D. University of Louisville, 1879; a member of the Arkansas Medical Society; for two terms surveyor of Faulkner County; for two terms alderman of Conway; and for six terms president of the local school board; died at his home in Conway, January 23, from heart disease, aged 59.

Thomas Jefferson Shoemaker, M.D. Kentucky School of Medicine, Louisville, 1865; a Fellow of the American Medical Association, and one of the founders of the Ohio Valley Medical Association; died at his home in Morganfield, Ky., January 29, from organic heart disease, aged 76.

Mark T. Clay, M.D. Indiana Eclectic Medical College, Indianapolis, 1886; of Little Rock, Ark.; died suddenly in his buggy, January 15, from heart disease, aged 58.

James O. R. Carley, M.D. Hahnemann Medical College, Chicago, 1885; a member of the Kansas Medical Society; died at his home in Winchester, January 12.

Isaac S. Becker, M.D. Albany (N. Y.) Medical College, 1856; health officer of Altamont, N. Y.; died at his home at that place, January 13, aged 84.

Henry E. Zielly, M.D. Geneva (N. Y.) Medical College, 1849; formerly of Chilton, Wis.; died at his home in Spokane, Wash., Nov. 18, 1913, aged 87.

David T. Collier (license, Missouri, 1884); for more than half a century a practitioner; died at his home in Licking, January 4, aged 77.

Matthew Mark Kannon, M.D. Bishop's College, Montreal, 1879; of Los Angeles; died in the Sisters' Hospital in that city, January 10.

John D. Pulliam, M.D. Jefferson Medical College, 1861; of Plentiful, Va.; died in Richmond, January 15, from pneumonia, aged 76.

W. H. Franklow, M.D. Memphis Hospital Medical College, 1892; died at his home in Shiro, Tex., January 9, from pneumonia, aged 42.

Comfort E. Rutherford, M.D. Eclectic Medical Institute, Cincinnati, 1886; died at his home in Peru, Ind., Nov. 17, 1912, aged 82.

Harvey W. Swales, M.D. Medical College of Ohio, Cincinnati, 1891; died at his home in Logan, Ind., January 6, aged 43.

Marriages

William H. Roberts, M.D., Terre Haute, Ind., to Mrs. Louisa V. Zink of West Terre Haute, February 2.

Peter Hubert Cremer, M.D., Cannon Falls, Minn., to Miss Delia Noel of Mazeppa, Minn., January 29.

Fred Selby Perrings, M.D., to Miss Alice Biebinger, both of St. Louis, at Clayton, Ill., January 20.

Edward Freeman Walsh, M.D., to Mrs. Abbie W. Follette, both of St. Paul, Minn., February 4.

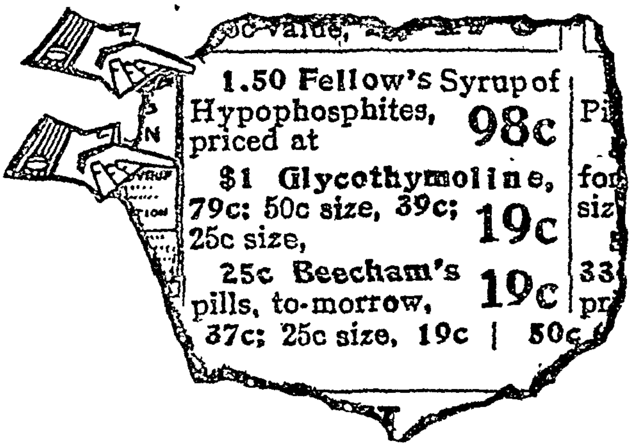
Clyde M. Zink, M.D., to Miss Sarah E. West, both of Louisville, at Indianapolis, February 3.

W. B. Carr, Jr., M.D. to Mrs. Tevis M. Elliott, both of Washington, D. C., February 2.

The Propaganda for Reform

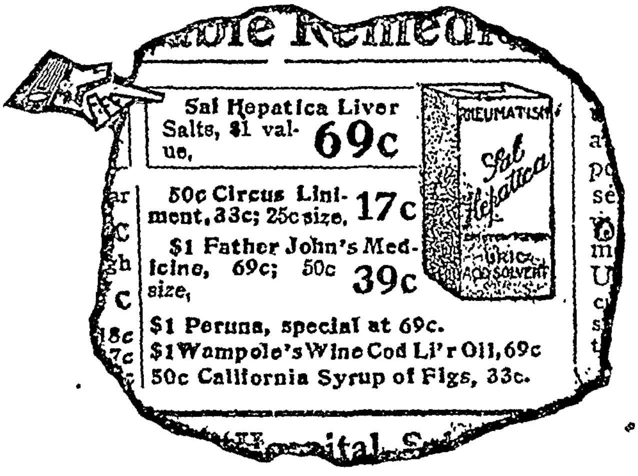
In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

WHEN IS A PATENT MEDICINE?



1.50 Fellow's Syrup of Hypophosphites, priced at 98c
$1 Glycothymoline, 79c; 50c size, 39c; 25c size, 19c
25c Beecham's pills, to-morrow, 19c
37c; 25c size, 19c | 50c

Some physicians and especially some medical journals seem to have difficulty in correctly classifying certain proprietary medicines. The drug departments of department stores find the problem a simple one. The reproductions shown above and below are of portions of a full-page advertisement in Chicago newspapers of Feb. 8, 1914. Fellows' Syrup of Hypophosphites, Glycothymoline and Sal Hepatica look perfectly at home with Peruna, Circus Liniment and Beecham's Pills



Sal Hepatica Liver Salts, $1 value, 69c
50c Circus Liniment, 33c; 25c size, 17c
$1 Father John's Medicine, 69c; 50c size, 39c
$1 Peruna, special at 69c.
$1 Wampole's Wine Cod Li'r Oil, 69c
50c California Syrup of Figs, 33c.
RHEUMATISM
Sal Hepatica
URIC ACID SOLVENT

SOME MORE FRAUDULENT OBESITY CURES*

Lucile Kimball

Lucile Kimball of Chicago comes to the obese with the message, "I can make your fat vanish by the gallon." Her claims are the stock claims of the "obesity cure" fakers of the "drugless" type. It is unnecessary, Lucile tells the fat-burdened, to change their method of living. All that is needed to remove their superfluous flesh is to take the Lucile Kimball home obesity treatment!

> ". . . my home treatment is not exercise or diet . . . eat any kind of meat, vegetables, salads, pastry, fish, fowl, nuts, candy that you want—when you want it. Drink what you want—when you want it. I don't interfere with your food or drink. No bending over, rolling, playing golf, horseback riding or doing exercises of any kind. Sit in your chair at home or in your chair at your office—and the fat will vanish from you by the pint, quart, and gallon. It goes away rapidly. It melts from your cells."

---

* These, with two other items to be published *next week*, will be incorporated in the pamphlet "Obesity Cure Fakes," price 10 cents.

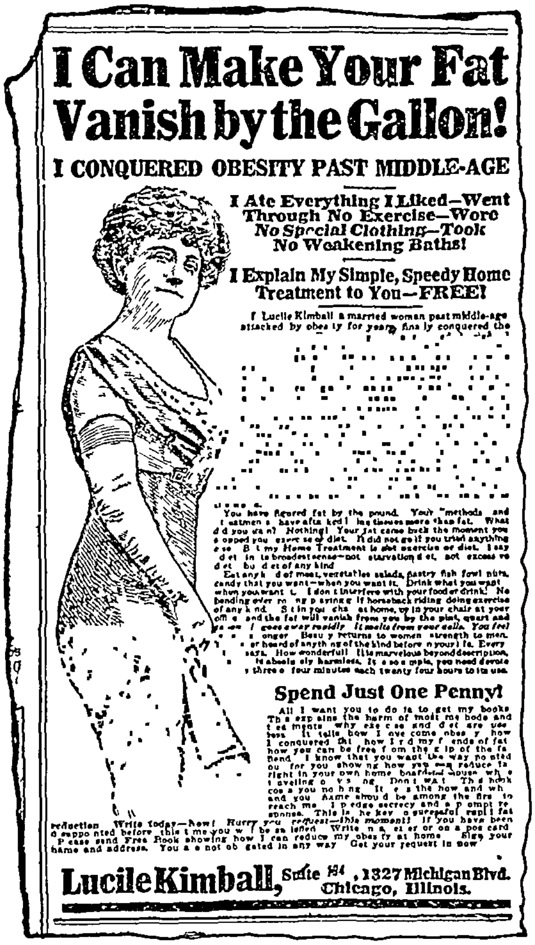
In her advertisements, Lucile pleads with her prospective victims not to send any money

> "Don't send a penny I will return it"

Like other frauds of this type, this "treatment" is entirely *different from every other "treatment"* It is essentially a "home remedy" "I am a home body," says Mrs Kimball, "opposed to the work of charlatans"—doubtless on the ground that competition is undesirable

To those who answer her advertisement Lucile Kimball sends a complete set of follow up letters The first letter describes the "cure's" simplicity

> "It does not attack living tissues It does not tear away muscle and healthy cells It simply converts your fat into an emulsion and passes it through your liver into your colon and out with your waste"



I Can Make Your Fat Vanish by the Gallon!

I CONQUERED OBESITY PAST MIDDLE-AGE

I Ate Everything I Liked—Went Through No Exercise—Wore No Special Clothing—Took No Weakening Baths!

I Explain My Simple, Speedy Home Treatment to You—FREE!

Spend Just One Penny!

Lucile Kimball, Suite 84, 1327 Michigan Blvd. Chicago, Illinois.

Truly a marvelous physiologic feat "And think of having to pay *only* Ten Dollars for this full and complete obesity treatment"

In the second letter Lucile rehashes that hoary anecdote about the Londoner who tried to sell sovereigns at a shilling apiece, but was unsuccessful because the public suspected a trick Says Lucile

> "I am offering you the equivalent of a gold sovereign for a cheap inexpensive little shilling Don't be too wise to see the bargain"

Therefore, "send your ten dollars . hurry it along do it while the spirit is on you" Letter three is of the "scare" type, an attempt to frighten the obese into taking the treatment Moreover, the price is reduced

> "Now I am going to give you an opportunity to secure this full treatment of mine, fully guaranteed, for only seven dollars . "

Letter four brings the price down to $5, letter five to $3 25, letter six to $1 79—providing the money is sent within three days—letter seven extends the time limit of the $1 79 offer

> "This is my final price—just $1 79, prepaid, I will never make you another offer This treatment cannot be purchased for a penny less"

In spite of this, letter eight comes, offering "this regular ten dollar treatment for only one dollar"

This is the last of the follow-up letters If the victim fails to send the dollar, Lucile Kimball charges the account up to profit and loss Here, in brief, are the offers made to those who answer the Lucile Kimball advertisements

Letter 1. Only $10 for "lifetime's complete mastery over fat"

Letter 2 Send $10 "while the spirit is on you"

Letter 3 Only $7 "Easily worth a dozen times this price"

Letter 4 "Send only $5 by express or post office money order Send your order to day, my friend"

Letter 5 $3 25 "If I could make the price any lower I should be delighted to do so"

Letter 6 $1 79 "Must be done within three days from the time you receive this letter"

Letter 7 $1 79 "Have decided to extend my offer" "I will never make you another one"

Letter 8 Only $1 "Hasten your order"

And what is the Lucile Kimball home obesity treatment? Dr Wiley asked this question, and to answer it had the "treatment" analyzed He gave the result of the examination in an article by Miss A L Pierce and himself in *Good Housekeeping* for January, 1914 Here it is, in brief

Pink Pills Reported to consist principally of red pepper, menthol and bitters, probably gentian or quassia

Brown Tablets These the chemists declared to be an old-fashioned *cathartic pill of the aloin type*

Powder This consisted, according to the chemists, of a mixture of soap, Epsom salt and washing soda

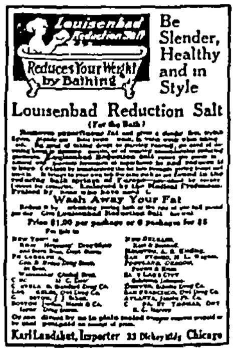
Surely much ado about nothing! We leave it to Lucile Kimball to explain the *following discrepancies* between facts and claims "No internal . . dosing", "No internal medicine" How about the purgative pills and the bitter tonic? "You don't have to take any special kind of bath" *What about the strong alkaline bath* powder consisting of soap, washing soda and Epsom salt?

Summed up the Lucile Kimball Home Obesity Treatment is palpably fraudulent and utterly worthless

Louisenbad Reduction Salt

Louisenbad Reduction Salt is sold by one Karl Landshut, Chicago It is a white powder and comes in tin boxes containing 14 ounces and costs $1 a box According to the label, Louisenbad Reduction Salt is

> "An obesity remedy for the reduction of superfluous fat without the use of drugs dieting or exercise"



Louisenbad Reduction Salt

Reduces Your Weight by Bathing

Be Slender, Healthy and in Style

Louisenbad Reduction Salt

(For the Bath)

Wash Away Your Fat

Karl Landshut, Importer Chicago

The stuff is supposed to be put *in the bathing water and baths are* to be taken "twice a week or oftener" A tablespoonful of the "salt" to a bathtubful of water is the amount prescribed This artistic touch is added to the label

> "Should the baths reduce faster than three lbs per week, they should not be used more than twice a week"

As a supplementary "treatment" it is urged that *the unsweetened juice of half a lemon should be taken on the same days* that the baths are taken The prospective purchaser is asked to believe that Louisenbad Reduction Salt has these powers

> "Removes superfluous fat and gives a slender form and stylish figure"
>
> "Enters the pores in a natural way, prevents formation of superfluous fat and reduces it where it exists by transforming the fat into strength giving blood and muscle"

The preparation was examined by the Association's chemists who reported, in part, as follows:

"*From the analysis* (made in the Association's laboratory) it appears that Louisenbad Reduction Salt has essentially the following composition:

Sodium sulphate, anhydrous (dried Glauber salt)	72.4 per cent.
Sodium chlorid (common salt)	11.2 per cent.
Potassium chlorid	16.4 per cent.

"The approximate cost of 14 ounces of such a mixture would be about 10 cents."

It is hardly necessary to say that taking a bath in a tubful of water in which a tablespoonful of a mixture of Glauber salt, table salt and potassium chlorid has been dissolved would have no other effect than that obtained from bathing in the same amount of water without the mixture. Two such baths a week would produce no appreciable effect in the diminution of weight of any individual who was not extremely dirty.

Correspondence

An Endowment Fund

To the Editor:—In contemplating the great humanitarian work which the Association and THE JOURNAL are doing—the propaganda for reform, the publication of Nostrums and Quackery, the work of the Council on Medical Education, the educational campaign against the social evil—I am impressed of late with this one thought: If the Association, with its limited resources, could accomplish so much in so short a time, what might we expect of it if its resources were large and secure! What, if we had a great endowment fund, might we expect from the coming years! What vast possibilities lie dormant for the lack of the one needful thing—money! How many people of great wealth, big-hearted, big-souled—"sun crowned, who live above the fog in public duty and in private thinking"—who would gladly bequeath liberal sums to a fund which could be used for such great and lofty purposes! Surely there is no greater service to mankind than that which this Association stands ready and pledged to perform if it had the wherewithal to do it. Why can we not establish such a fund and endeavor in every way available to let it be known, and for what purpose it exists? Why would it not be right and proper to seek out philanthropy and lay bare the great human needs that should be ministered to, and the great human purposes and ideals which this Association has in offering such ministry? I know not but this may be already a fixed policy with the Association: Already others may have had their own dreams and formulated them into fixed plans. If so, I am an intruder. If not, does the suggestion seem to merit some consideration?

S. A. FOOTE, M.D., Bay City, Tex.

Blood Transfusion in 1492?

To the Editor:—Under this title Dr. J. L. Joughin (THE JOURNAL, Feb. 14, 1914, p. 554) quotes from Villari's "Life of Savonarola" a passage purporting to give an "accurate record" of the first transfusion. The following passage from A. H. Mathew's "Life and Times of Rodrigo Borgia" (1912, Brentano's, p. 66) throws a somewhat different light on the same incidents:

"On the evening of July 25, 1492, the good-natured and incompetent Pope Innocent VIII passed away. It is related that, during his last illness, the operation for transfusion of blood was unsuccessfully performed. This, however, is an error arising from the forgetfulness of two important facts: (1) that the idea of this operation could not occur to any one to whom the circulation of the blood was unknown; (2) that the phenomenon of the circulation of the blood was not discovered until the seventeenth century. Raynaldus and Infessura say that a certain Jewish physician undertook to restore the Pope's health; for this purpose he drew all the blood out of three young boys, who immediately died. With their blood he prepared a draught which, in spite of the doctor's protestations, failed to improve the sick pontiff's condition. The saving virtue of drinking human blood was no new idea."

Mathew then quotes from Tertullian's "Apologeticus" a passage referring to the practice of drinking, as a cure for epilepsy, the fresh blood of criminals killed in the arena.

C. R., Chicago.

"The Doctor Can Wait"

To the Editor:—In "A Poor Man's Bank," by Walter Prichard Eaton, *The American Magazine* for February, one reads the following:

> To sit at a board meeting of the Atlanta Loan and Savings Company is an experience worth having. The secretary reads the new applications. John Doe applies for a loan of $100. He is a clerk, with a salary of $60 a month. His endorsers are a fellow clerk and his employer, or perhaps three or four of his fellow clerks. He has a wife and baby. The report on his character is good, and his endorsers are sound.
>
> "What does he want the money for?" somebody asks.
>
> The secretary reads from the application: "Baby's been sick, operation cost $50. Borrowed from shark. Owes doctor $50, drugs $12, grocer $9, rent $12, shark $47. Wants to pay as much as he can. Shark has been threatening him."
>
> "Who's the doctor?"
>
> "Dr. Smith."
>
> "I know him," says one of the directors. "He'll wait till we can get the man clear of his other debts. I'll see Smith to-night. That would reduce the indebtedness to $80. Lend him $80."
>
> "Hang it up! On to the next!" cries Director Sawtelle. The vote is unanimous.

Picturing the bluff, confident delivery of this director, one cannot help but be amused. The amusement, however, changes to something very like resentment on reflecting how his view is accepted generally. The director and John Doe will as a matter of course agree that Dr. Smith's services were the most necessary and highly trained. Yet the doctor is to wait. Are either of these men able to reveal the supernatural source from which Dr. Smith is to derive his support?

Changing this lay point of view is a duty incumbent on him who implanted it—the physician.

LAWRENCE SCHLENKER, M.D., St. Louis.

The Comparison Ocular

To the Editor:—In the article by Dr. D. G. Healy, on "A Comparison Ocular" (THE JOURNAL, Nov. 29, 1913, p. 1958), stress is laid on the date since which it has been used (May, 1912), and it is stated that the instrument has been constructed by Messrs. Bausch & Lomb, from the idea suggested by Dr. Healy. Furthermore, it is stated that it antedates by six months the comparison microscope devised by Dr. Thoerner in Germany. The Comparison Ocular described, is not new but is over twenty years old. It was made by C. Reichert, Vienna, on the suggestion of Dr. Henri von Heurck. It is fully described on pages 105 and 106 in his book, "The Microscope, its Construction and Management." The English edition was published in 1893 by Crosby Zockwood & Son, London, England, and the D. Van Nostrand Company, New York.

A. TRAEGER, New York.
American representative, ERNST LEITZ.

[The foregoing letter was referred to Dr. Healy who writes: I am glad to have this information regarding the origin of the comparison ocular. When I suggested the comparison ocular to Messrs. Bausch & Lomb, I was not aware that such an ocular had been made, and the idea as such was original with me.—ED.]

Radium Prices in Germany.—Consul Milo A. Jewett of Kehl notes that the Strassburg Hospital and University some time ago bought 200 mg. of radium at $76 per milligram, and has bought 100 mg. more, which will cost at present prices $98 per milligram (or at the rate of $3,000,000 an ounce, troy weight).—*Daily Consular and Trade Reports.*

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ASTHMA FROM ANAPHYLAXIS—HAY-FEVER SYMPTOMS FROM HORSE-SERUM

To the Editor:—In The Journal, Jan. 31, 1914, in Therapeutics, under the heading "Anaphylaxis," there appear some statements such as those in the following quotation:

"When antitoxin is indicated in diphtheria, or horse-serum in hemorrhage, one should be sure to inquire whether or not the patient is an asthmatic or a sufferer from hay-fever, and especially if horse emanations cause either of these conditions. If such is the case, all horse-serums are positively contra-indicated."

Please give me (1) the scientific proof (or sufficient scientific indication) that asthma and hay-fever are caused by anaphylaxis, and (2) the scientific proof (or sufficient scientific indication) that inhaled dust or emanations from horses can cause anaphylaxis (and thus cause asthma and hay-fever).

George E. Barnes, M.D., Herkimer, N. Y.

Answer.—1. Asthmatic symptoms are prominent in typical anaphylactic shock. In guinea-pigs contraction of the bronchioles is one of the characteristic phenomena of anaphylactic shock. In severe forms of serum disease the attack may begin with acute asthmatic symptoms, as in De Besche's case. In persons with "idiosyncrasies" with respect to various food substances such as eggs, strawberries, etc., acute asthmatic attacks associated with urticarial and other skin reactions may occur after the ingestion of the offending substances. Cases of so-called egg-asthma are described by Landmann, Moro, Koessler and others. In view of this state of facts it seems not unreasonable to believe that in susceptible, that is, sensitive persons, various bacterial proteins from foci of chronic infection also may cause asthmatic symptoms. In some cases it is supposed, too, that minute particles of foreign proteins suspended in the air may cause asthmatic reactions when inhaled by sensitive persons. This would seem to be illustrated in the case of persons who have asthma when they come into close contact with horses, go into tunnels, etc. In guinea-pigs primary sensitization, as well as the explosive anaphylactic shock, has been produced by spraying foreign serum into the trachea and lungs. For these and other reasons there would seem to be "sufficient scientific indication" to conclude that asthmatic attacks are the result of the direct action on the bronchioles and respiratory tract of substances developed in the course of parenteral protein digestion and hence of similar pathogenesis as "enteritis anaphylactica" and "conjunctivitis anaphylactica."

That hay-fever or hay-asthma is the expression of an anaphylactic reaction to certain pollens is indicated, first, by the fact that animals may be rendered anaphylactic with respect to pollen proteins, and secondly, by the fact that typical acute hay-fever with characteristic local reactions on the part of the nasal and other mucous membranes, as well as itching and urticarial eruptions, has been produced experimentally by the injection of the proper pollen into a hay-fever victim (Dunbar's experiment), the reaction occurring within a few minutes, whereas in a person not subject to hay-fever, such injection had no effect. The best explanation we have of this "idiosyncrasy" is that the hay-fever victim for some reason had ferments in his blood that split the pollen proteins so that toxic substances were produced, which caused the symptoms of hay-fever by their action on the respiratory mucous membranes, as well as cutaneous reactions like those familiarly seen in serum disease.

2. While we have no direct proof that dust and emanations from horses can cause the primary sensitization necessary in order to produce anaphylaxis experimentally, there are recorded quite a number of cases of abnormal sensitiveness to such emanations, generally taking the form of asthmatic manifestations and symptoms like those of typical hay-fever, and it is in just such cases that the injection of horse-serum has been followed by most violent reactions. In such cases sensitization must have been caused in some way, but just exactly how this occurred, whether from inhalation of emanation or otherwise, is not known. It is of course not quite correct to say that emanations from horses can cause hay-fever. What was meant is that in certain persons these emanations may cause symptoms like those of hay-fever. Such persons are likely to be taken with grave disturbances on the injection of horse-serum.

"THE LESSON IN ANATOMY"

To the Editor:—In connection with articles on Rembrandt's "Lesson in Anatomy" would say that I never examined picture closely, but heard that the origin and insertion of one of the muscles in picture is not anatomically correct. Is assertion correct?

J. F. E. Colgan, M.D., Philadelphia, Pa.

SCANDINAVIAN MEDICAL JOURNALS

To the Editor:—Please give me a list and the subscription prices of Swedish, Norwegian and Danish journals.

Ralph Holm, M.D., Wolbach, Neb.

Answer.—Following is a list of periodicals and the subscription price of each:

Hospitalstidende.—Publisher, Jacob Lunds Boglade, Pilestræde 6, Copenhagen, Denmark; editor, T. Rovsing; weekly; price, $8.25 a year, plus postage.

Ugeskrift for Læger.—Publisher, Den alm. danske Lægeforenings Bureau, Gl. Strand 44, Copenhagen, Denmark; editors, H. Mygind, V. Scheel and H. Maag; weekly; price, $5.35 a year, plus postage.

Norsk Magazin for Lægeridenskaben.—Publisher, Steen'ske Boktrykkeri, Christiania, Norway; monthly; price, $5 per volume, plus postage.

Tidsskrift for den Norske Lægeforening.—Publisher, Centraltrykkeriet, Christiania, Norway; editors, P. Aaser and R. Hansson; price, $4.05 a year, including postage.

Hygiea.—Monthly; $5; Stockholm.

Nordiskt Medicinskt Arkiv.—Irregular; 30 marks; Stockholm.

Upsala Läkareförenings Förhandlingar.—Irregular; 10 crowns.

ADMINISTRATION OF CALCIUM

To the Editor:—Please answer the following questions:

1. Which is the best salt of calcium to give intramuscularly or subcutaneously when you want calcium effect in case of calcium insufficiency? What about the irritation?
2. What are the dosage and dilution of solution of these salts when thus given?
3. Which is the best salt of calcium to give orally for an acidemia and for a calcium insufficiency?
4. What dosage orally?
5. Are the lactate and glycerophosphate equally good for a systemic effect of calcium for the nerves?
6. What foods have the largest percentage of calcium?

George F. Way, M.D., Buffalo, Ill.

Answer.—1. The lactate of calcium is less irritating than the chlorid, and would probably be the best salt to give intramuscularly or by hypodermic injection. It is doubtful if the demand for calcium is ever so pressing as to require hypodermic injection.

2. A dose of 5 grains should be sufficient. Calcium, when administered internally, is rapidly excreted; hence there could be no object in giving large doses. It may be given in a 4 per cent. dilution.

3. The lactate and chlorid of calcium are commonly selected for internal administration. Of these the lactate is less irritating, and is preferable.

4. The dose is 0.5 gm., or 7½ grains.

5. Yes; the effect so far as the calcium is concerned will be the same. There is no good evidence that glycerophosphate has any special effect on the nerves or other functions.

6. Milk, yolk of egg, peas, egg-albumin, potato, wheat, beef. This order is determined by the proportion of calcium in the dried substance and would need some modification if we consider the foods in the form in which they are eaten.

FRANCIS ADAMS

To the Editor:—Please furnish me with some information touching the life of Francis Adams, LL.D., surgeon, the translator and editor of the works of Hippocrates, published under the auspices of the Sydenham Society of London.

Charles Turner Sands, M.D., Las Cruces, N. Mex.

Answer.—Francis Adams (1796-1861), born at Lumphanan, Aberdeenshire, Scotland, and known as "Adams of Banchory," from the village in which he practiced, and also "the Deeside scholar," was a graduate of Kings College, Old Aberdeen, and, after studying medicine, became an M.R.C.S. (London) in 1815. Although described as a good practitioner and a skilful operator, his specialty was his classical learning as applied to medicohistorical research. From the age of 15 on he is said to have devoted seventeen hours a day to the study of Virgil and Horace, reading each six or seven times in succession, and during his professional life he managed to read "almost every Greek work which has come down to us from antiquity, except the ecclesiastical writers." He had a large share in the compilation of Dunbar's Greek Lexikon (1840), to which he contributed a valuable list of Greek names of animals, plants, etc.; was the author of "Hermes Philologus" (1826), on the difference between Greek and Latin syntax, and published two volumes of translations of Greek poems (1820, 1853); but his most important works are his well-known editions of Paul of Aegina (1834) and Aretaeus (1856) with text, commentaries and translations, and particularly his English translation of the genuine works of Hippocrates (1849), with valuable historical introduction and notes, which is the standard English translation for all practical purposes. These three performances are the most important British contributions to the history of Greek medicine in Adams' time, and have not been surpassed since that time. Adams was a good surgeon, obstetrician and botanist, although it is said that he obstinately declined to believe that the fetal heart-sounds can be heard by auscultation. In his memory, there have been erected a monument at Banchory (put up by public subscription), a granite obelisk, with Latin inscription, and a marble bust in the University of Aberdeen.

GLYCID—ACETOL

To the Editor:—In THE JOURNAL, Jan. 31, 1914, p. 409, Abstract 40, mention is made of glycid and acetol. I do not find these terms in my dictionary. What are these preparations?

Q. D. V.

ANSWER.—Glycid is the oxid of hydroxypropene. The following formulas will make this relation plain:

Propene is $CH_2{:}CH.CH_3$; hydroxypropene is $CH_2{:}CH.CH_2.OH$, and the oxid of hydroxypropene has the following formula:

$$CH_2\overset{\diagup O \diagdown}{\text{—}}CH.\,CH_2.\,OH.$$

It is isomeric with lactic aldehyd and with acetol.

Acetol is hydroxy-acetone, an alcohol with the formula $CH_3.CO.CH_2OH$. The corresponding formula for acetone is $CH_3.CO.CH_3$. Acetol is isomeric with lactic aldehyd and with glycid. Both glycid and acetol lack only an atom of oxygen to change them into lactic acid: $CH_3.CH(OH)COOH$.

The close relation of these substances with lactic acid led to the question whether they might be transformed into lactic acid and thus lead to the formation of sugar. The experiments of Geer, Witzemann and Woodyat showed that this supposition is incorrect.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

STATE LAWS ON COMMUNICABLE DISEASES

One of the most important functions which any department of our federal government can perform is the collection and publication of valuable information regarding conditions in the states. Owing to our peculiar form of government, there are many activities which, in other nations, are under the jurisdiction of the national government, but in this country are purely state functions. The regulation of public health except in matters in which the entire nation is affected, has always been considered to be one of the prerogatives of the state, and any efforts to enlarge the public health jurisdiction of the federal government always encounter a certain amount of opposition, regardless of the merits of the proposition, from those who were opposed to any extension of federal power at the expense of state authority. Practically everyone is agreed, however, that the collection and distribution of information by the federal government cannot possibly impair the authority of the state, but can be of great service in bringing about a more accurate knowledge of conditions. Entirely aside from any views which may be held on the possibility or advisability of a national Department of Health, or of further expansion of the present Public Health Service, there can be no difference of opinion among reasonable persons as to the value of any efforts which the present Public Health Service may make to collect and make available accurate information regarding health conditions in the different states. One of the most important subjects which could possibly be taken up in this connection is the study of state public health legislation. A most valuable contribution to the literature on this subject has just been issued by the United States Public Health Service, in the form of *Public Health Bulletin 62.* It is entitled "Communicable Diseases: An Analysis of the Laws and Regulations for the Control thereof in Force in the United States." It has been compiled by Dr. J. W. Kerr, Assistant Surgeon-General of the Public Health Service, with the assistance of Mr. A. A. Moll. It includes, first, a comparative study and analysis of the federal, state and territorial laws and regulations for the control of communicable diseases; secondly, court decisions enforcing and interpreting these laws, and thirdly, the complete text of all federal, state and territorial laws relating especially to the control of communicable diseases. The compilation is complete up to July 1, 1913. The value of this bulletin to public health officials and to those interested in public health legislation can hardly be overestimated. The detailed and accurate comparison and analyses of the laws will surely have a marked influence on the drafting of bills on this subject in the future, as well as on the interpretation and enforcement of laws already enacted. In the analysis of the laws and comments on their development, the authors point out the fact that all communicable diseases are preventable, but that an attempt to bring about such prevention solely through the enactment and enforcement of laws is impossible. The enforcement of laws in this country requires the support of public opinion, which, in turn, requires the education of the public by the presentation of facts showing the necessity and value of such laws. The authors also point out the necessity as an administrative measure of drafting public health laws on the most advanced and broadest scientific knowledge, leaving the regulation of technical details to the boards. They also show that reasonable appropriations are necessary for modern public health work, and that failure to provide sufficient funds practically amounts to nullification of the law, while ample provision in this respect will make it possible to prevent a large proportion of deaths now caused by communicable diseases. Finally, there must be uniformity in legislation and cooperation in administration between the federal, state and local health authorities. The history and development of public health legislation on communicable diseases is also carefully studied, it being shown that it is the intent of Congress, generally speaking, simply to cooperate with the states in this field, and not in any way to supersede them in the sovereign exercise of their police powers. It is recognized that this is a fruitful field for discussion, and that the extension of federal powers under the "commerce clause" is but a slow and doubtful process at best. That there must be cooperation with the federal government is evident on account of the possibility of spreading disease through interstate commerce, in order to control the interstate sale of serums, to secure uniformity of action among the states through annual conferences with the federal health authorities, and the like. In the matter of national quarantine, however, it is recognized that the federal health authorities must be supreme. This involves the control of quarantine, in foreign ports, on the high seas and in domestic ports of entry. It is also necessary for the federal government to control the public health questions involved in the restriction of immigration; but even the assumption of these powers as a purely federal function, and their evolution into a nation-wide system, has required nearly a century since the adoption of the Constitution. One sees in this a suggestion, although there is no statement to this effect in the bulletin, whether the tendency of public health legislation in this country is not perhaps at first an attempt toward uniformity and cooperation by the states with ultimately a recognition of the necessity of universal federal control. The entire bulletin is of the utmost value to the student of public health legislation and administration. The sections citing court decisions and the reprint of the texts of the laws are of self-evident value. The bulletin is a most creditable piece of work both to the Public Health Service and to Dr. Kerr, under whose supervision it was compiled.

PUBLIC HEALTH MEASURES IN STATE LEGISLATURES

Last winter probably marked the climax of weird, erratic and uncontrolled efforts at state public health legislation. In the forty-three state legislatures which met at some time during 1913, an indefinite and indeterminate number of bills on public health topics were introduced. How many there were it is impossible to say accurately. There were over one thousand and probably nearly twelve hundred. In practically every state, bills on almost every conceivable phase of public health, especially its popular aspects, were before the legislature. Many of the bills were, no doubt, carefully drafted, and if their passage could have been secured they would have been valuable additions to the laws of the state. Most of them, however, represented hobbies and theories, rather than facts. To expect legislatures composed mainly of laymen without any scientific knowledge to separate the wheat from the chaff was asking an impossibility. Some of the states undoubtedly secured valuable additions to their public health laws, but in many cases the patience of the legislatures was exhausted through the presentation of loosely drafted measures not in shape for serious consideration. A conspicuous example is the Wisconsin law requiring a health certificate of the groom as a condition for the issuing of a marriage-license. Whether the "horrible example" presented by Wisconsin has had a deterring influence on the state legislatures, or whether the moderation shown is simply a reaction from the extremes of a year ago, it is markedly apparent that the number of proposed public health measures this year is greatly reduced.

According to the best available information the legislatures are at present in session in Georgia, Kentucky, Maryland, Massachusetts, Mississippi, New Jersey, New Mexico, New York, Ohio, Rhode Island, South Carolina and Virginia. In May the Louisiana legislature will meet. So far the bills on public health topics are few. In Georgia, a bill providing for the medical inspection of schoolchildren has passed the senate. The bill provides that medical services for such inspection are to be furnished free, that no permanent appointments are to be made and that no facilities for inspection are to be provided by the state. Apparently, the physicians of Georgia are willing to donate their services, feeling sure that the results secured will justify a continuance of this work. In Kentucky, a bill moving the office of the State Board of Health to Frankfort is before the senate, the committee having reported against it. In Massachusetts, a bill limiting the sale of mercuric chlorid tablets has been introduced. In Mississippi, bills are under consideration for the establishment of county sanatoriums for tuberculosis and providing sanitary closets for rural schools. In New York, the usual antivivisection bill has been introduced by those who have been carrying on a professional antivivisection campaign for years past This bill was introduced by Senator Herrick of New York City, and provides for a commission of seven to investigate the entire question of animal experimentation. The commission is to consist of two physicians "practicing vivisection," two persons connected with societies for the prevention of cruelty to animals and three attorneys. In New Jersey, a bill similar to the Wisconsin law has been introduced, requiring each party to a marriage contract to present a certificate from a reputable physician certifying their freedom from disease. A bill has also been introduced defining the practice of medicine, under the medical practice act, so as to include "those who hold themselves out to the public as able to diagnose, treat, operate or prescribe for any injury, disease, or who shall use the designation M.D. or M.B." In Ohio a bill has been introduced requiring practicing physicians to pass an examination every two years in order to retain their license. In Virginia, a bill has again been introduced removing the occupation tax on physicians. The medical profession of the state has been endeavoring for several years to secure the repeal of this measure. An optometry bill has also been introduced. The state board of health has asked for a special appropriation to establish a sanatorium for negro consumptives. In South Carolina, a bill similar to the Wisconsin law regulating marriage was killed in the senate.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Connecticut: New Haven, March 10. Sec., Dr. Charles A. Tuttle, New Haven. Homeopathic: New Haven, March 10. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Eclectic: New Haven, March 10. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Maine: Portland, March 10-11. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Massachusetts: Boston, March 10-12. Sec., Dr. Walter P. Bowers, Room 159, State House, Boston.

Wyoming: Laramie, March 10-12. Sec., Dr. H. E. McCollum, Laramie.

Medical Scholarships at the University of Virginia

The current catalogue of the University of Virginia announces that under the will of Dr. Cumberland George Herndon, two scholarships named after the testator's father, the William A. Herndon scholarships, have been founded in the Department of Medicine of that institution. Candidates must be unable to defray expenses of their medical education except by borrowing or doing outside remunerative work during the session, and must signify their intention of entering the medical service of the Army or Navy of the United States. The scholarships provide for the necessary expenses of the student during the four years of his medical course, and will yield approximately from $425 to $450 per annum, according to the income from the fund. They will be awarded as vacancies occur. One will be awarded in September, 1914.

Texas June Report

Dr. W. L. Crosthwait, secretary of the Texas State Board of Medical Examiners, reports the written examination held at Austin, June 24-26, 1913. The number of subjects examined in was 12; total number of questions asked 120; percentage required to pass, 75. The total number of candidates examined was 147, including 10 osteopaths, of whom 138 passed, including 9 osteopaths, and 9 failed, including 1 osteopath. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
Birmingham Medical College	(1912)	78
University of Colorado	(1913)	91.7
College of P. and S., Atlanta	(1905) 84.5; (1913)	80
Chicago College of Medicine and Surgery	(1913, 2)	82, 82
University of Louisville	(1911) 78; (1913)	75.4, 76, 77, 80, 80.5, 89.9.

* No grade given.
† No college given.
‡ To come before review committee.

The following questions were asked:

ANATOMY

1. Give the course and distribution of the trifacial nerve. 2. Name and give the origin of the arteries supplying the stomach, small intestines, large intestines. 3. Give the course and branches of distribution of the femoral artery. 4. Name the ligaments of the

knee-joint. 5. Name the structures forming the larynx. 6. Give the formation of the brachial and lumbar plexus and name main branches given off from each. 7. Enumerate the bones forming the orbit. 8. Give origin, insertion, nerve-supply and action of the pronator radii-teres muscle. 9. Describe the diaphragm, its principal openings and nerve-supply. 10. Give the characteristic points of cervical, dorsal and lumbar vertebrae.

HYGIENE

1. What are the diseases by preventing which the average of human life could be prolonged? 2. How would you disinfect a room after occupancy by a patient with an infectious disease? 3. What methods do you adopt to prevent infection during labor, and what instructions do you give for the care of the mother and child during the lying-in period? 4. What are the parasitic diseases that may be caused by meat insufficiently cooked? 5. What are the principal pathogenic bacteria found in milk? 6. How would you test milk for impurities? For adulterants? 7. What is the difference in appearance between healthy and spoiled meat? 8. Give five reasons from a hygienic standpoint why the fly should be swatted. 9. In what ways is meat adulterated or "doctored"? 10. What amount of floor-space should be allowed in a schoolroom for each child? Give proper height of ceilings of schoolrooms, and what should be least window area in proportion to size of window?

MEDICAL JURISPRUDENCE

1. For medicolegal purposes "mortuary law" is classified into four divisions; name them. 2. What do you understand by the term "suggillation?" Give its medicolegal significance; describe a post-mortem in a medicolegal case. 3. Give methods employed in the identification of blood-stains and examination of blood; differentiate between human and animal blood. 4. Give four common causes of death from wounds; differentiate between punctured and penetrating wounds inflicted before and after death. 5. Differentiate post-mortem findings of carbonic-acid gas and sulphuretted hydrogen gas. 6. Name seven forms of medicolegal pregnancy; give medicolegal importance of the uterus in the dead. 7. Give conditions or grounds warranting "justifiable abortion"; give the necessary safeguards to be observed, so as not to be held responsible for assault and criminal abortion. 8. In the consideration of insanity and its relations to the law give the two important questions to be determined; give distinction between intellectual and moral insanity. 9. Give four classifications or divisions of monomania and define each. 10. As applied to life insurance, what is meant by "material concealment?" Give relations of suicide to life insurance.

PHYSICAL DIAGNOSIS

1. State physical signs of pyloric stenosis. 2. Differentiate lobar from bronchopneumonia. 3. Give the physical signs of Raynaud's disease and describe the different grades. 4. State the principal diagnostic symptoms of scarlatina, diphtheria, variola, rubeola. 5. What is Cheyne-Stokes respiration? Argyll Robertson pupil? Widal's test? Wassermann reaction? Koplik's spots? 6. State briefly the principal diagnostic points of tetanus, exophthalmic goiter, chorea. 7. What are the plantar reflexes? What is the diagnostic value of the plantar reflexes? 8. In aortic and mitral insufficiency, where is the murmur he[illegible]hat is its direction of transmission? 9. [illegible] in ascites and cystic ovary. 10. Give [illegible]rebrospinal meningitis and acute anterio[illegible]

PHYSIOLOGY

1. Give average normal temperature, rate of pulse and of respiration in (*a*) the infant, (*b*) the adult, (*c*) the aged. 2. Define protoplasm, and give the characteristic properties of living protoplasm. 3. Describe the heart-sounds and state to what they are due. 4. What digestive changes take place under the influence of saliva and of gastric juice? 5. State the origin and function of bile; give quantity secreted in twenty-four hours. 6. Describe the process by which digested food is absorbed. 7. Describe the physical properties of the blood and name its constituents. 8. State origin of urea in the body; give average amount excreted in twenty-four hours. 9. Give function of (*a*) medulla oblongata, (*b*) the cerebellum. 10. Describe in detail how the placenta performs its functions.

PATHOLOGY

1. Name some of the tissue changes incidental to old age. 2. Give the pathology of acute lobar pneumonia. 3. Name some of the most essential lesions found in acquired syphilis. First, second and third stages. 4. Name the chief findings in enteric fever. 5. Give the pathology of chronic interstitial pneumonia. Give the pathology of hemorrhoids. 7. Name the morbid cha[illegible] of the pituitary body. 8. What morbid [illegible] from disease of the adrenals? 9. Nam[illegible] changes resulting from cerebral hemorrhage. 10. What is an opsonin? 11. What do you understand by productive inflammation? 12. What is the pathology of diabetes mellitus? Answer as many as ten of the above questions.

SURGERY

1. What are the symptoms of air embolism? Give treatment. In what region are surgical operations most liable to be followed by this condition? 2. Give the symptoms of simple, compound and compound comminuted fracture and treatment of each condition of tibia and fibula. 3. Give symptoms of patient indicating tracheotomy; then intubation, and describe fully each operation. 4. Diagnose an infective exudate of the pericardial sac, beyond controversy, and state how you are going to relieve this condition. 5. Differentiate tuberculous and syphilitic synovitis. Give structural changes that induce symptoms of, and describe in detail Bassini's operation for strangulated, oblique inguinal hernia. 7. Differentiate concussion, comprehension and congestion of the brain. 8. Give differential diagnosis of pelvic peritonitis and impaction of feces. 9. Give signs and symptoms of cervical rib, and state how cervical rib produces signs and symptoms. 10. How should a dissecting wound and attendant blood-poisoning be treated? What is rational treatment of suppurative abscess from its initial symptom? Give symptoms and treatment of psoas abscess, and state with what condition it may be confused.

GYNECOLOGY

1. Give the (*a*) clinical diagnosis, (*b*) microscopic diagnosis of carcinoma of the cervix uteri. 2. Differentiate between tubal pregnancy and ovarian cyst. 3. Name a[illegible] of the uterus and briefly outline an adeq[illegible]rrection of retroversion of the uterus. 4. Wl[illegible] demand hysterectomy? 5. Give a clinical [illegible] chronic pyosalpinx and outline an adequat[illegible]elief of same. 6. Define amenorrhea, dysmenorrhea, menorrhagia, metrorrhagia and vicarious menstruation. 7. Describe clinically and pathologically three types of endometritis. 8. Describe the ovary (*a*) as to its anatomic relationships; (*b*) as to its physiologic function. 9. A woman aged 35 has an intermenstrual flow or discharge streaked with blood; mention four probable causes of same and make differential diagnosis with reference to malignant disease. 10. Give the etiology, pathology and clinical diagnosis of chronic cystitis of women.

OBSTETRICS

1. Describe the changes that take place from the time the ovum is impregnated to the beginning of the second month. 2. Give the cause and mechanism of labor. 3. How would you manage a shoulder presentation? 4. Define ectopic gestation. Differentiate same from uterine pregnancy. 5. Give etiology and management of eclampsia. 6. Define uterine inertia. (*b*) What do you understand by primary and secondary inertia? Describe same. 7. Give management of third stage of labor. 8. How would you do a podalic version? 9. Give management of puerperal stage. 10. Give etiology of hyperemesis and management of same.

CHEMISTRY

1. Complete the *following* equation: $NaCl + H_2SO_4 =$.......... and name resultant compounds. 2. Differentiate ethyl alcohol from methyl alcohol, giving formula of each. 3. Name three extensively used carbon compounds which under certain conditions are dangerous to life. 4. State source of cyanogen gas and name two most important compounds. 5. Give a reliable test for nitrites. 6. (*a*) From what is the alkaloid muscarin derived? (*b*) Give symptoms of poisoning, (*c*) fatal dose, and (*d*) physiologic antidote. 7. How would you test water suspected of sewage contamination? 8. Describe a reliable method of determining the quantity of urea in a specimen of urine. 9. Describe a test for, (*a*) albumin, (*b*) sugar, (*c*) pus, (*d*) blood, (*e*) indican and (*f*) chyle. 10. Name chemical antidote for nitrate of silver, or lunar caustic, and say how it acts.

Minnesota January Report

Dr. Thomas S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, Jan. 7, 1914. The number of subjects examined in was 10; total number of written questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 6, of whom 3 passed and 3 failed. Ten candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Chicago	(1909)	87
Detroit College of Medicine	(1906)	82

Book Notices

STUDIES CONCERNING GLYCOSURIA AND DIABETES. By Frederick M. Allen, A.B., M.D. Cloth. Price, $9. Pp. 1179. Boston: W. M. Leonard, 1913.

"The present work," the author says, "represents three years of research in the Laboratory of Preventive Medicine and Hygiene of the Harvard Medical School." It is in no sense a clinical study and contains no direct clinical observations. Concerning the scope of the monograph Allen says, "It aims primarily to present the results of research."

The volume is large, and the greater part is devoted to an elaborate presentation of the literature. This review represents a stupendous and commendable work agreeably done and possessing a genuine value for the investigator who desires to grasp what has been accomplished in an unfamiliar department of diabetic investigation. As arranged by Allen and interlarded with his original comment and speculation, it forms suggestive and entertaining literature, revealing many facts which have not received the emphasis due them, and, indeed, sending the imagination on many a rapid flight. This constitutes the most commendable feature of the book.

In general it may be said that the experimental work has been mainly on the administration of different sugars by different methods (oral, subcutaneous, intravenous, etc.), to different species of laboratory animals in a state of health and in the glycosuric states produced by such procedures as piqûre, epinephrin, phlorhizin and pancreatectomy. Observations were made on the intensity of the glycosuria and on the diuretic or antidiuretic effects of the doses given. There are also many data and much comment concerning the operation of pancreatectomy—total and graduated. A few salient features may be picked out for discussion.

Allen says that if about four-fifths of the pancreas be removed in such a way that the remaining fifth is left in communication with the ducts or duct, this fifth will serve to prevent the occurrence of diabetes, as is known to be the case when other parts are left, but that in this instance the intestinal digestion and general nutrition are only slightly impaired and the dog remains in exceptionally good condition. In the course of time diabetes develops as in other experiments of the Sandmeyer type. This scheme provides apparently a valuable technic for the preparation of diabetic material for laboratory purposes.

Another feature on which Allen lays particular stress is what he terms the "paradoxical law." "Briefly, this law is that the more sugar is given, the more is utilized. Limits of tolerance in non-diabetic animals are all apparent, not real. There is no real limit of the power of utilization of sugar, except death. The law applies to all species of animals, to all methods of administering sugar, and to all sugars and carbohydrates, provided they can be utilized at all. The paradoxical law of dextrose distinguishes sharply between diabetic animals and every type of non-diabetic animals. The limits of tolerance in diabetic animals are real and not apparent. In totally diabetic animals, an injection of dextrose causes an increment of glycosuria not only equal to, but frequently greater than, the injected dose. In milder diabetes not only is the proportion of excreted to injected dextrose generally high, but the assimilation may be made worse instead of better by overdoses." Allen also attaches great importance to the diuretic or antidiuretic effects of doses of sugar when given by different methods in different conditions. We quote:

"The observations of numerous investigators, that all the common sugars are diuretics when given intravenously, was verified. But all the freely utilizable sugars when given otherwise than intravenously (orally, subcutaneously, intraperitoneally, also, according to Halasz, rectally) are antidiuretics, i. e., they diminish the output of urine. In other words, as respects diuresis, these sugars, when given intravenously, obey the law of crystalloids, and when given otherwise they obey the law of colloids. On the basis of this diuretic test, diabetes was distinguished experimentally from the following forms of glycosuria." Alimentary, hunger, toxic, phlorhizin, thyroid and nervous glycosuria are enumerated.

"The explanation proposed for these phenomena is that dextrose exists in the normal body in a state of colloid combination; as a colloid it can be utilized by the tissues, and it diminishes diuresis like other colloids. It assumes the colloid form in passing through any living membrane, it never circulates in crystalloid form in the normal organism except for a certain length of time after direct intravenous injection. In the diabetic organism, dextrose circulates as a free or very poorly combined crystalloid, in this state it is not available to the tissues, and it is a diuretic like other crystalloids."

The chief facts brought out by Allen have in most instances been noted before, but probably never have received the emphasis, or exactly the interpretation here given them. That free crystalloid sugar is diuretic is not a new conception. That the antidiuretic effect of utilizable sugars in health is due to sugar in colloid combination, if expressed before, has not gained currency. The facts that Allen employs in his arguments are in the main correct, but not wholly so, the interpretation offered is by no means an inevitable one, although highly interesting. Most clinicians who have seen much diabetes will recall cases in which the glycosuria and diuresis did not run parallel even in the severe cases of genuine diabetes mellitus, and those familiar with phlorhizin will hesitate to accept Allen's conclusions regarding it.

When the ratio of the velocity at which sugar enters the blood to that at which it is utilized exceeds a certain value diuresis may be expected—in health or in diabetes. When the rate of entry is less than, equal to, or but little greater than the possible rate of utilization, the opposite effect may be expected—in health or in diabetes, or in phlorhizin glycosuria. It surely never has been proved that there is no limit to the rate at which sugar can be made to burn in the body. In a case of severe diabetes a relatively slow entrance of sugar into the blood (oral administration) might be expected to produce the same effect which in health is attainable only by a very rapid entry (intravenous injection). And so in some cases of diabetes the alimentary or subcutaneous methods may suffice to cause diuresis whereas in health the intravenous method must be resorted to in order to obtain parallel results, and in phlorhizin glycosuria diuresis can be produced with dilute sugar solutions slowly given.

Allen's proposal that these phenomena are ascribable only to the power of "living membranes" to link up sugar into a colloidal combination with a specific "pancreatic amboceptor," lack of which constitutes "a condition *sui generis*" known as diabetes would seem to be a step away from the sun of the pure sciences, the expression of a physicochemical problem in terms of Ehrlich's hypothesis. Nevertheless there is food for thought in Allen's concept, in his arguments favoring the idea that normal blood sugar is in some sort of colloidal combination, and in his analysis of other phases of the diabetic problem. The book will have a stimulating effect.

KURZER LEITFADEN DER PSYCHIATRIE. Für Studierende und Aerzte. Von Dr. Ph. Jolly, Assistenten an der Psychiatrischen und Nervenklinik in Halle a. S. Paper. Price, 4 marks. Pp. 240. Bonn: A. Marcus & E. Webers, 1914.

This is a concise compend of psychiatry which aims to give the chief and generally recognized facts regarding mental diseases, especially those of practical importance, avoiding theoretical considerations as far as possible. Seventy-two pages are devoted to general psychiatry, with consideration of general etiology, symptomatology, diagnosis, pathology, prognosis and treatment, giving clear definitions of terms used in psychiatric literature and detailed and practical directions for taking the history and making physical and mental examinations. Descriptions are given of tests for all the principal physical and mental symptoms and signs encountered, and brief statements are made as to the significance of each one and the mental diseases in which it is apt to be found. The author does not discuss the subject of psychanalysis. A special portion deals with individual conditions.

Miscellany

Standardizing Mercuric Chlorid Tablets.—The frequent cases of poisoning by mercuric chlorid tablets sold to the laity in the drug-stores, usually under the name of antiseptic tablets, has brought forth many suggestions as to the manner in which these tablets should be prepared and dispensed in order to give them a distinctive character and of calling attention to their poisonous properties. A large number of these tablets are put on the market by different pharmaceutical manufacturers in different shapes and colors, some in distinctive bottles or packages and containing various quantities of the poisonous salt. M. I. Wilbert of the United States Public Health Service in *Public Health Reports, Nov. 14, 1913,* discusses the subject of these poisonous tablets and says that at present there is sufficient legislation, if enforced, to serve as a reasonable safeguard in connection with their sale. Thirty-eight states include corrosive sublimate specifically in the laws designed to restrict the sale of poisons, and only in the law of Utah are corrosive sublimate tablets exempted from registration in the poison register. During 1913, Oregon, Nevada and California enacted modified poison laws and specifically enumerated tablets of corrosive sublimate in the poison schedule required to be registered when sold. They also specifically enumerated "antiseptic tablets containing corrosive sublimate." It has been suggested that a type of corrosive mercuric tablets or pastils be introduced into the Pharmacopeia of the United States. The German Pharmacopeia has such a preparation of mercuric chlorid. The pastils are to be colored a bright red with anilin dye, must have a cylindrical shape and be twice as long as thick. They are to be wrapped individually in black paper bearing the German equivalent of the word "poison" in white letters. The weight of the tablets must be stated, and they must be dispensed in glass bottles or tubes. It is suggested that the inclusion of an official tablet of corrosive mercuric chlorid in the U. S. Pharmacopeia need not interfere with the established trade of manufacturers, and Wilbert suggests that if manufacturers would label their preparations so as to indicate the presence of highly toxic substances and suggest to purchasers the need for keeping them apart so that they would not be mistaken for other substances, then perhaps no additional legislation would be required on the subject. It is also suggested that newspapers should not publish the details of the kind of poison used in cases of accidents or intentional poisoning.

Coal-Mine Accidents in the United States.—Foreign countries in which mining is carried on extensively have had official statistics of coal-mine accidents for many years: Belgium since 1831, Great Britain since 1851, Germany since 1852, France since 1853 and Austria since 1875. Until 1912, no official figures as to coal-mine accidents in the United States were gathered by the United States government, but beginning with that year the federal Bureau of Mines has compiled the figures, and in Bulletin 69 a tabulated and classified statement of coal-mine accidents is given. It includes not only figures for 1912 as gathered by the Bureau of Mines, but also figures for years since 1896 as obtained from state mine inspectors, operators and other sources. A tabulated statement of the production of coal, number of men employed, number killed, etc., for the years 1896 to 1912 shows an almost steady rise in the number killed per thousand of men employed, from 2.84 in 1896 to 3.15 in 1912, with high points of 4.88 in 1907 and 4 in 1909, the highest figure, in 1907, being accounted for by four exceptionally disastrous mine explosions. This increase in the death-rate from accidents may be accounted for partially by the increase in the production of coal per man. In 1896, for instance, every man employed produced 2.64 tons of coal per day, whereas, in 1907 the daily production for each man was 3.06—an increase of 16 per cent. with its consequent greater risk. Stated in another way, however, it is shown by the table that in 1896, 170,000 short tons were produced for each death, while in 1912 the amount was 233,000 short tons. Though during all this time increased attention was given to mine safety and prevention of accidents, yet the rapid change in methods and the enormous increase in production were not accompanied by corresponding measures to decrease risk. In 1908, Congress authorized the United States Geological Survey to investigate the causes of mine explosions with a view to increasing safety in mining. The work was placed under the direction of the Bureau of Mines and in 1910 a separate bureau on mine safety work was established. Since 1908 there has been an annual decrease in the number of men killed per million tons of coal mined. The most marked improvement was in 1912, when the number of men killed was less than any other year since 1906, and the death-rate per million tons of coal mined was the lowest on record, and 359 men (13.2 per cent.) less than the figures for 1911, in spite of the fact that there were more men employed in the mines and more coal mined than in any previous year. The death-rate per thousand men employed in 1912 was 3.15, as against 3.73 the previous year. The improvement in later years has been brought about, as the bulletin states, by a combination of causes the principal of which has been more effective and more efficient mine inspection on the part of state mining departments and state mine inspectors, supplemented by greater care on the part of both the operators and the miners. Further improvement will depend largely on the care exercised by all those concerned in the coal-mining industry.

The Work of the Bureau of Child Hygiene.—In New York it is found that 36 per cent. of infant mortality occurs during the first month, and it has been concluded that the majority of the babies die because the mothers were physically unfit to bear healthy children or because of their ignorance of the proper care of their infants. The bureau, therefore, has established a center of instruction for nurses at one of the milk-stations, and the nurses have been assigned to canvass the neighborhoods and persuade expectant mothers to place themselves under medical care as early in pregnancy as possible. These cases are reported to the district doctors of the department of health, the mothers are instructed, in detail, with regard to diet, fresh air, exercise, clothing, etc., and they are impressed with the importance of nursing their infants. In normal cases, visits are made by the nurses every ten days before the birth of the children, every three days after for a month, and in abnormal cases as often as may be necessary. The mothers are then requested to enrol their children at the milk-station, at which they are cared for during the first and second years. Thus far 175 mothers have been enrolled, and twenty-five children have been cared for in this manner.

Public Health Work in Porto Rico.—W. W. King of the United States Public Health Service, in *Public Health Reports,* Dec. 12, 1913, makes a report of the work of the Institute of Tropical Medicine and Hygiene of Porto Rico, to Oct. 31, 1913. The institute was organized under the provisions of the legislative assembly of Porto Rico, for the purpose of studying tropical diseases incident to that island, and is the outcome of the control of that island by the United States, following the work of the medical corps under Dr. Bailey K. Ashford in hookworm disease. The plan of the institute for work in the islands comprised three months of teaching, instruction of sanitary officials, inspectors, etc., three months of expeditionary work in the interior of the mountainous districts and six months of work at the laboratory and hospital at San Juan, where the permanent headquarters are located. The expedition in the mountains was for the purpose of studying the diseases of the interior, the establishment of a rural outdoor medical service and the education of planters and laborers in elementary hygiene and sanitation. It has been estimated that from 50 to 70 per cent. of the population of the rural districts were in need of medical attention with practically none provided. The headquarters of the expedition is at Utuado on a large sugar plantation, where a well-equipped dispensary and hospital with thirty beds has been established. In order to induce the people to come to the dispensary established, arrangements were made for the treatment of hookworm cases which brought large numbers of the people to the dispensary. Other diseases of all sorts were then studied and treated among the 7,500 patients who presented themselves. Among the diseases of tropical nature studied were schistosomiasis and "la bonita," which is a name given by the country people to an affection whose chief symptom is anasarca. This disease is limited to the country districts and sometimes occurs epidemically. A nephritis seems to be the chief feature of the disease. Sprue, amebic dysentery, malaria and trachoma are among the other diseases studied.

Medicolegal

Representatives Who May Waive Privilege

(Oldenburg v. Leiberg (Mich.), 142 N. W. R. 1076)

The Supreme Court of Michigan says that the statute of that state, as amended in 1909, reads: "No person duly authorized to practice physic or surgery shall be allowed to disclose any information which he may have acquired in attending any patient, in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon: Provided, that after the decease of such patient, in a contest on the question of admitting the will of such patient to probate, the heirs at law of such patient, whether proponents or contestants of his will, shall be deemed to be personal representatives of such deceased patient for the purpose of waiving the privilege hereinbefore created." Assuming that heirs at law of a decedent are both contestants and proponents of the will, may the contesting heirs, or the proposing heirs, or either of them, waive the statute privilege of the deceased, the patient?

Before the statute was amended, it had been held by this court that information acquired by observation while the physician was in attendance on his patient, as well as communications made by the patient to the physician, was excluded, that the rule established by the statute is one of privilege, which the patient may waive, and that what he may do in his lifetime those who represented him may also do for the protection of the interests they claim under him, but that, in a will contest between a legatee and a contesting heir at law, the heir at law is not the representative of the deceased, and is an adverse party, with no right to waive the statute privilege.

This being the state of the law, the legislature amended the statute in the manner hereinbefore indicated, and the court holds, because it thinks no other ruling will give effect to all of the provisions of the amendment, that any heir at law, proposing or contesting the probate of a will, is, for the purpose of waiving the privilege, a personal representative of the deceased. With the wisdom of the legislation the court has nothing to do, and therefore does not attempt to contrast the alleged beneficial with the harmful results which may attend the application of the statute in cases which may be supposed.

Agreements to Split Fees Void as Against Public Policy—Cross-Examination—Including in Suit Fees for Assistant at Operation

(McNair vs. Parr (Mich.), 143 N. W. R. 42)

The Supreme Court of Michigan reverses a judgment recovered by the plaintiff for professional services in operating on the defendant for hernia and on his daughter for appendicitis, and grants a new trial. The court says that the defendant claimed, among other things, that at the time the causes of action arose there existed between the plaintiff and a Dr. Stuck, who was then the defendant's physician, an unlawful agreement and combination, by which the plaintiff and Dr. Stuck were to divide the fee which the defendant was to pay the plaintiff for the surgical operations and professional visits mentioned in the plaintiff's bill of particulars, which combination was unlawful and void, as contrary to public policy, and in violation of the statutes and common law of the state.

It was the claim of the defendant that Dr. Stuck could not be the agent of both of the parties to the suit, while he was at the same time assisting in these operations as the family physician of the defendant; that he could not draw pay from both parties, without the knowledge of all the facts by the defendant; that any tacit understanding or agreement between the two physicians of any division of the plaintiff's fees between them would be against public policy and void; and that the defendant had a right to show that the plaintiff had charged an unreasonable sum for his services, in order to divide his fees with Dr. Stuck. That such a contract is against public policy the defendant cited a number of Michigan cases, also 9 Cyc. 481, 482; 34 Cyc. 1430. The court is of the opinion that the cited authorities support the claim of the defendant, and that any agreement of the plaintiff to split his fees with Dr. Stuck, without the knowledge of the defendant, would be void as against public policy.

The court also thinks that too strict a rule was applied in the cross-examination of the plaintiff, to the prejudice of the defendant, when the latter sought to show a tacit understanding between the plaintiff and Dr. Stuck, growing out of their former practice in other similar cases, in the matter of a division of fees. Considerable latitude should be allowed in cross-examination when fraud is claimed.

There was error, too, in a refusal to charge the jury that they could not allow the plaintiff any money for the services of Dr. Stuck rendered at these operations. The plaintiff, after testifying that his bill was only for his personal work, changed his position and testified, in answer to a question by the court, that his bill included Dr. Stuck's bill. If the judgment rendered in the plaintiff's favor were to stand, the defendant might have to pay twice for the services of Dr. Stuck. That they were included in that judgment might be presumed under the charge of the court; but the value of such services did not appear. Dr. Stuck was not a party to or bound by that judgment, and might maintain a suit against the defendant for his services.

Liability of Surgeon of Charitable Institution for Leaving Spring from Packer in Uterus

(Wharton vs. Warner et al. (Wash.), 135 Pac. R. 235)

The Supreme Court of Washington directs that a judgment be entered against the defendant Warner for damages for malpractice. The court says that he was employed at a sanatorium as the surgeon in charge thereof, and that in the treatment of Mrs. Wharton, by a curettement of the uterus. he used a uterine packer, and a spring therefrom, some 12 inches in length, became detached from the machine and was packed into the uterus and allowed to remain therein for a period of fifteen days.

Passing to the law of the case, it may be announced as one of the fundamentals of the law that negligence is never presumed, but that it must be affirmatively established by competent evidence.

It is equally well settled that, when a physician and surgeon takes charge of a case, he impliedly represents that he possesses, and the law imposes on him the duty of possessing and exercising, reasonable skill and learning, that is, such skill and learning as is possessed by the ordinary practitioner in that general locality, measured by the state of medical and surgical science at the time the service is rendered.

Tested by these principles, there was abundant evidence of Dr. Warner's negligence. Indeed, it would excite surprise had the jury returned a different verdict. The jury was warranted in finding (*a*) that he was guilty of negligence in leaving the spring in the uterus; (*b*) that he was negligent in failing to discover and remove it; and (*c*) that the packer with which he performed the operation was not then used by surgeons possessing average learning and skill in that locality.

It was argued (1) that whether a surgical operation was unskilfully performed is a question of science, and is to be determined by the opinion evidence of surgeons, and (2), in effect, that a bad result standing alone is no evidence of unskilful surgery From these postulates it was argued that there was no evidence to sustain a verdict against this defendant Both propositions are sound when soundly applied The reason is that in most cases a layman can have no knowledge whether the proper medicine was administered or the proper surgical treatment given Whether a surgical operation was unskilfully or skilfully performed is a scientific question If, however, a surgeon should lose the instrument with which he operates in the incision which he makes in his patient, it would seem as a matter of common sense that scientific opinion could throw little light on the subject So, in this case when a surgeon loses a metallic spring about 12 inches in length, and about 1/16 of an inch in width, in the body of his patient, and fails to discover and remove it, it would seem that a jury would have abundant justification for inferring negligence without the aid of expert testimony But, putting this view aside, the court thinks that the evidence set forth was insufficient to support the verdict

But the medical missionary and benevolent society, organized *for charitable purposes only*, which conducted the sanatorium and which the evidence showed exercised reasonable care in selecting Dr Warner, could not be held responsible for his negligence The same rule applies when the plaintiff pays for the services rendered, where the amount received is not for private gain, but to accomplish more effectually the purposes for which the charity was founded

Manslaughter in Death from Unlawful Administration of Morphin to Alleviate Pain

(Silver vs State (Ga), 79 S E R 919)

The Court of Appeals of Georgia holds that when a person, in violation of the statute, administers morphin by means of a hypodermic syringe to another in such quantity as to cause death, he commits an unlawful act, and a conviction of involuntary manslaughter in the commission of an unlawful act would be authorized It is no defense that in the administration of the drug the intent was not to cause death, but to alleviate pain Whether or not the administration of morphin is an act evil in itself would, of course, largely depend on the amount and the circumstances under which it was administered Administration in small amounts and to alleviate pain might be construed as a beneficent act, but administration without this purpose, or to one who habitually uses it, might well be considered a wrongful act However this may be, under the Georgia statute the administration of morphin in any quantity or for any purpose, except under prescription as provided by the statute, is unlawful, and the penal code declares that "involuntary manslaughter shall consist in the killing of a human being without any intention to do so, but in the commission of an unlawful act" The administration of morphin without a prescription being unlawful under the state statute, it follows that when death ensues from such unlawful administration of morphin, the person so administering the morphin is guilty of involuntary manslaughter in the commission of an unlawful act

Presumption that One Is Not a Physician

(Miller vs State (Miss), 63 So R 269)

The Supreme Court of Mississippi, in affirming a judgment of conviction of the appellant Miller of unlawfully selling cocain, says that his complaint was that the state failed to prove that the person to whom the sale was made was not a regular licensed physician or dentist, and that the sale was not made on a physician's prescription If the sale was made on the prescription of a physician, that fact lay peculiarly within the knowledge of the defendant, and consequently, it devolved on him, and not on the state, to establish it

There was no direct evidence that the negro boy to whom the sale was made was not a physician or dentist, but the presumption was that he was neither, and therefore, if he was a physician or dentist, it devolved on the defendant to prove it The state withholds from the mass of the people the right to practice the professions of medicine and of dentistry, and grants it only to exceptional persons, of every one of whom it is certainly true that at one time he was not allowed to practice as such There was here, therefore, a double prima facie presumption first, that the person to whom this sale was made did not belong to the exceptional class of persons to whom the right to practice medicine or dentistry had been given, and, second, that as at one time he had no such right he has none now

NATIONAL CONFERENCE ON RACE BETTERMENT

Held at Battle Creek, Mich, Jan 8 12, 1914

(Concluded from page 569)

The Negro Race

Mr Booker T Washington, Tuskegee, Ala · Few races in history have been subjected to so many sudden, violent and trying changes as has the American negro There was the transition from Africa to America, from free life to slave life, and then from slave life to free life Then there has been the change which a large proportion of the race has experienced of moving from the South into the North In spite of all these changes the negro has lived and is living and intends to live The white race must be a little patient with the negro, because he is trying to readjust himself to all the physical, industrial, social and moral conditions The negro is worth saving In order to be most helpful to it, the white race should try to keep most of the negro race in the country districts, out of contact with large, complex city life The next thing is to keep whisky away from my race I have observed the effect of the use of liquor on my people, and I have no hesitation in saying that it should be kept from them I would also ask you to use your influence to keep patent medicines away from my race These three things will help my race The two races are going to stay in this country, we are going to help or hinder you, and we wish you to help us to get to the point where we can help you

Community Hygiene

Rev Caroline Bartlett Crane Kalamazoo, Mich No community lives unto itself Community hygiene may depend in no small part on the neighboring but unneighborly community A proper division of the function and proper functioning in each division of public health work is of vital concern to every community Each community must not only do its own part, but must also maintain a partnership with other communities under the supervision of the state which granted the municipal corporation all the rights and privileges which it possesses, and which may naturally be looked to to maintain cooperation between these corporations And states may naturally expect the national government to act strongly in behalf of the general welfare

The Health Certificate—A Safeguard Against Vicious Selection in Marriage

Dean Walter T Sumner, Chicago · We guard our business with a great deal of care If a group of men desire to form a partnership they must secure permission from the legislature, if a man or a group of men desire to carry on a municipal trade they must secure a license, if a man in the city of Chicago desires to carry on only an insignificant street trade he must vouch for his responsibility at the city hall If this same man desires to marry he goes down to the city hall alone and gets a license. He may be a degenerate or an epileptic, or the diseases of the social evil may be coursing through his veins. These people are allowed to marry and propagate their kind, and to pass on to succeeding generations the physical, mental and moral deficiencies which they possess. We are giving much time and attention to the question of environment. We should give much attention to nurture. In face of the fact that we safeguard marriage or selection in marriage by no laws and by no public attention, is it strange that we have in our public institutions three million abnormal people, costing this nation two hundred million dollars a year for their care, and that they are increasing far and beyond the proportion of the increase of the population in this country, large as that increase is? The demand for a health certificate before marriage will come about by legislation, and this is effective just as it is backed up by public opinion. Public opinion to-day is not well informed with regard to the need of safeguarding marriage selection. Education of the public is the great hope, and the greatest agent for education in this country to-day is the press.

The Relation of Physical Education to Race Betterment

Dr. D. A. Sargent, Cambridge, Mass.: In nearly all the countries of the world there is a steady decline in the birth-rate. The most prosperous communities, even in our own country, are not reproducing a native population equal to the death-rate, and in some of the towns of New England the death-rate actually exceeds the birth-rate. If it were not for the influx of foreigners and those born in rural communities our great towns and cities would soon be depopulated. Some of the causes of this are: (1) poverty and inability to support a family of children; (2) luxurious living and the indisposition to take on the cares and responsibilities of reproduction; (3) living in apartments and communities where children are often regarded as a nuisance; (4) the preoccupation of both sexes with professional work; (5) love of ease, sports and amusements and the selfish gratification of all the senses; (6) inability from lack of health, or the possession of a bad inheritance. Physical education can bring the hereditary weakling up to par. An increasing number of the better classes in America are awakening to the importance of having more children and giving them a physical as well as mental training.

Factory Degeneration

Rev. Newell Dwight Hillis, Brooklyn: The recognition of the deterioration of our factory people has been recognized for many years. The cure rests on the reform of industrial conditions. It all rests with the woman who can rear a healthy baby. The only cure for the factory-class degeneration in this or any other country is rebuilding of factory-class civilization.

The High Cost of Living As a Factor in Race Degeneracy

Dr. J. N. Hurty, Indianapolis: The high cost of living has a bearing on race degeneracy. If we could raise the price of diseased meats and whisky so high that they could not be bought, that would be an advantage. We place too much faith on the doctor and on medicine. We think that medicine can undo the wrong that we have done the body. It can only repair. It cannot remedy or remake. We must have medicine, but we must view it from a different angle. We are obsessed with the idea of cure. To eradicate from men's minds the idea that they ever can experience perfect cure after disease or injury would do a great deal of good. When we attempt to tell people that they must not get sick, and that getting sick is weakness, they go to the next doctor, who will give them a drop of medicine. Let us get away from that idea.

Tobacco a Race Poison

Dr. Daniel Lichty, Rockford, Ill.: Tobacco is a narcotic poison; every part of the plant is poisonous, and only a few poisonous plants excel it in deadliness. Eighty per cent. of the adolescent and adult male population are enamored of its potency. Man by the excessive use of tobacco makes himself a member of the human scrap-heap. Narcotic indulgence means race degeneration. Tobacco-using is drug slavery. Tobacco, alcohol and syphilis leave the same scar on progeny.

Some Suggestions for a More Rational Solution of the Tuberculosis Problem in the United States

Dr. S. Adolphus Knopf, New York: In spite of all efforts, 200,000 people are dying annually from tuberculosis in the United States. Of these, fifty thousand are tuberculous children. Estimating the average age of these fifty thousand children dying annually from tuberculosis at about 7½ years, and figuring the cost to parents and the community for each life as only $200 per annum, the financial loss thus represented is $75,000,000. These children have died before they have been able to give any return to their parents and the community. Twenty million children attend public schools in the United States, of whom 600,000 are in need of open-air instruction or sanatorium treatment. We can at present provide for about 2,000 of these tuberculous children.

The 150,000 adults who die annually of tuberculosis have been incapacitated for at least two years. At $1,000 per year, this would mean $300,000,000 uselessly spent in caring for people afflicted with a disease that might be prevented. Unless we make the cure of the disease lasting by judicious after-care, the money spent for sanatorium maintenance is a loss.

There should be a sufficient number of public parks and playgrounds in our great cities to counteract congestion and reduce it to a minimum. Medical schools should give special courses in the early diagnosis of tuberculosis. The man advertising fake consumption-cures should be treated as a dangerous criminal, for such he is. There should be state insurance against tuberculosis. The influx of tuberculous immigrants liable to become a burden to the community should be prevented by compelling all steamship companies to assure a clean bill of health for every immigrant brought to these shores, and to insure every immigrant against tuberculosis. Procreation of the tuberculous should be prohibited by law and the prevention of it taught to every tuberculous adult. Predisposing factors to tuberculosis, such as child labor, sweat-shop labor, too long working hours for both men and women, and bad housing conditions in tenements, apartments, lodging-houses and hotels in city and country must be combated by rational laws and their strictest enforcement. The same rigor should be applied to laws concerning proper ventilation and sanitation in workshops, factories, stores and public conveyances.

The Importance of Frequent and Thorough Medical Examination of the Well

Dr. Victor C. Vaughan, Ann Arbor, Mich.: Our country has a population of nearly one hundred millions. Millions of these are decent, respectable citizens—not altogether wise, but for the most part well-informed. Thousands are brutal in their instincts, criminal in their pursuits, and breeders of their kind. We assert that we are civilized, but there are those among us who would be stoned to death within less than twenty-four hours were they to attempt to live in a savage tribe. Decay and death come with advancing years. Those possessed of strength and health must bear the burden of those afflicted with poor health. The world has seen what has been done in Havana and the Canal Zone, where the most pestilential spots have been converted into healthful habitations. Scientific investigation has made these demonstrations, and the world applauds, but seems slow to make general application of the rules of hygiene. I look forward with confidence to the time when preventable diseases will be prevented, and when curable diseases will be detected and treated while curable.

The Effect of Alcohol on Longevity

Mr. Arthur Hunter, New York: Alcohol in moderate quantities is a food, but a very dangerous food. Even small doses of alcohol have a detrimental effect on muscular power. There is little doubt of the degenerating influence on the mental processes produced by alcohol, even in small quantities. The true way to determine the effect of alcohol is to find out how lives are shortened by the use of it. The insurance companies are completing an enormous investigation involving something like two million lives, to obtain information to enable them to elect risks with greater care, and also to charge extra premiums This investigation is being carried on by forty three life insurance companies In order to determine the effect of alcohol we must have some standard of measurement

Alcohol—What Shall We Do About It?

Dr **Henry Smith Williams**, New York I have no objection to alcohol as such—it has almost the formula of sugar But what I object to is its effects on the brain, mind and morals of the people The greatest dangers of alcohol are to the adolescent, and we should make it as nearly impossible as we can for the youth to secure it

Effect of Philanthropy and Medicine on Race Progress

Mr **Leon J Cole**, Madison, Wis The laws of heredity that are operative in the lower animals are also operative in man Which is the more important—environment or heredity? Biologists agree that results which are the effect entirely of environment are not inherited, but other conditions, environmental conditions, may affect the germ plasm What we mean by saying that environmental conditions are not inherited is that they are not inherited in any specific sense It has long been believed by the medical man that alcohol has directly a deleterious effect on the offspring Recent experiments have shown that alcohol, lead and certain other poisons may directly affect animals so that their germ cells are weakened This is not a specific inheritance It is simply a weakening of the germ plasm It is possible that other toxins, the toxins of certain diseases, may have a similar effect on the germ plasm, but I wish to emphasize the certain fact that this is not a specific effect It is a general deteriorating effect on the germ plasm, and as a result of it defective animals are born, which is also probably the case in man It is the work of the biologist and medical man to learn of the method of inheritance of these things, and of the method of control, and, finally, I think that mankind is going to accept those things which are easiest and compatible with ideals These methods cannot go contrary to ideals Medicine must go ahead in the course that it has, and charity must go ahead in the course that it has, but in both these lines we must have an eye to the future In later years medical science has turned its attention so much toward preserving life that it has given very little thought as to what it was doing to the race as a whole

The Function of the Dentist in Race Betterment

Dr **C N Johnson**, Chicago To better the race, we must better the individual by adding to his physical, mental and moral efficiency The condition of the teeth has much to do with the health of the individual A poorly nourished body must result in inefficiency, the result of decayed teeth is inefficient mastication, without mastication we cannot have good digestion, without digestion we cannot have assimilation, and without assimilation we cannot have nourishment It may seem a far cry from defective teeth to delinquency, but it is a logical sequence There is a very real danger to the individual and the community as the result of defective teeth and broken down roots left in the jaws Ninety per cent of schoolchildren have decayed teeth Our boards of health should give attention to this

Public Repression of the Social Evil

Mr **Graham Taylor**, Chicago We can estimate the magnitude of the social evil from the diseases which come directly from it into our hospitals, in hospitals for the blind, in institutions for the feeble minded, in infirmaries and insane asylums, and that gruesome, never ending procession of delinquents through our police stations and courts We can estimate the financial investment in commercialized vice, the forms those investments take, the profits that are made, the blackmail that is levied, the bribery of public officials, which is well known, mounting up into millions in our large cities But the half is never told

Segregation

Dr **Hastings H Hart**, New York Thousands of the insane are put into jail to "protect the community from danger"—but not one in ten is dangerous More than half the children coming into reformatories are in need of medical or surgical treatment It is less than six years ago that an investigation of the Lancaster School showed that probably 28 per cent of all the girls there were subnormal That led to an examination of other similar institutions, and now the fact is generally accepted that in our prisons and reformatories at least 25 per cent of the inmates are defectives, among our juveniles from 25 to 50 per cent, and in one institution where a psychologist was employed to examine the girls, 65 per cent were feeble minded These girls do not need reformatory treatment They need to be out in the open, have fresh air, have recreation, have a good time There are a multitude of feeble minded in the hospitals for the insane, and we are spending 50 per cent more for their care than necessary We no longer build asylums for the deaf and blind, but we build schools for them and educate them to become self supporting citizens The most important care of the community is the custodial care of the feeble minded girl who is perpetuating and multiplying her kind, and she is twice as prolific as the normal woman All the insane are being taken care of, but not the feeble minded, and the latter are twice as dangerous I do not know of any one who is more deserving of care than these girls of 16, 17 and 18, who have the mind of children of 7 or 8 and the body of women, who are pursued and hunted down and destroyed like rabbits

Relation of Eugenics and Euthenics to Race Betterment

Dr **Richard M Metcalf**, Oberlin, Ohio We must promote the gathering and safe filing of human inheritance records, which in the future will serve as the foundation of such practice of eugenics as shall prove wise and practical Among the great needs must be recognized scientific study of the principles of inheritance Marriage of certain individuals is unsatisfactory To what extent the state can intervene to prevent such marriage is a question which needs careful study

3 **Scarlet Red for Tuberculous Laryngitis**—Hinman uses an ointment, whose base is equal parts of sesame oil and petrolatum, with a dye strength of 10 per cent, and this is applied twice daily to the larynx The drug is said not to be irritating and the applications are not distressing Thus far he has not observed anything of a toxic nature, or, in fact, any untoward symptoms The first and most surprising result obtained was a very prompt relief of pain This was noted in every case in which pain had been present It was reduced in all cases and in some entirely relieved, so that patients were able to eat and drink with comfort In all cases but two, both of which were far advanced before treatment was instituted, and both patients dying very soon after, ulcerations showed a tendency to heal The general laryngeal congestion of several cases soon subsided and the hoarseness improved A few patients presented only infiltrations and

edema. After a few weeks of this treatment with scarlet red the swelling grew markedly less.

Hinman directs attention to the fact that they were the more incipient cases and that they improved generally during this time and therefore the local improvement may have been as much due to the general betterment as to the local effect of the dye, but it is reported because it is very possible that this drug may be shown to have some selective action through the unbroken mucous membrane. As yet all of Hinman's investigations and observations have been from the clinical standpoint and therefore the pathologic findings are not reported. Two patients who presented extensive ulcerative lesions of the larynx when they were admitted have since died. In one there was a decided lessening of pain and some improvement in the ulceration prior to his death, the other patient died shortly after beginning treatment, before results could be expected.

15 *Value of Blood Picture in Early Diagnosis of Measles, Especially in Relation to Question of Isolation. W. P. Lucas, San Francisco.

12. **Alimentary Disease.**—Vincent is convinced that by means of the bacteriologic examination of infants' stools he has arrived at a means of diagnosis which in respect to accuracy and precision is far superior to any other means. While the direct microscopic examination is most important and should never be omitted, it is not solely relied on. For the complete examination Vincent requires to determine the organisms that are dominant, by observing which of them appear when a portion of the dejection is transferred by means of the platinum loop to sterilized milk. Milk is the chief culture medium systematically employed.

Quite apart from specific treatment, the bacteriologic diagnosis influences the conduct of the case. In dealing with an intestinal condition due to dominance of the acid-forming organisms, the first line of treatment is the exclusion of all diet calculated to assist the lactic organisms. Raw milk must be forbidden. Cooked milk with the lactose reduced to a minimum amount is indicated. In such cases a reasonable amount of fat and a considerable amount of protein in the shape of caseinogen may be given. If this be given in the shape of milk the lactose may still be too much, and one may therefore employ a precipitated casein. In these cases chalk may be useful in contending with the excessive acid, and opium in minute amounts in the case of the young infant may be useful in calming the irritated intestine.

A favorite preliminary treatment in these cases at the Infants' Hospital is albumin water made with normal saline, termed "saline albumin." With this are combined a few teaspoonfuls of a diluted meat extract, while small doses of brandy are given at intervals. Opium is also given in small doses. Very gradually a normal milk diet is introduced, but throughout the treatment the dietetic and medicinal treatment is constantly checked by examination of the dejections. The precise treatment of the conditions arising from dominance of the colon organisms depends a great deal on the age of the infant. In the young infant—under 6 months, and particularly under 4 months—the intestinal conditions are rather apt to undergo very rapid changes. In a moderate case of colon toxemia where the constitutional symptoms are not severe, it is a mistake to undertake too active treatment with a view to the rapid suppression of the dominant organisms. As a rule treatment with cultures of the lactic organism is not indicated. It is better to adopt measures favoring the gradual development of the lactic organisms by dietetic management than by the administration of pure cultures. If the case is obstinate and the colon dominance persists despite the administration of raw milk containing a good proportion of lactose, then the administration of cultures is indicated. According to Vincent's observations, children fed on boiled milk are more liable to contract tuberculosis, and especially the more serious forms of tuberculosis, than children fed on raw milk, and he believes the reason for this is the chronic toxemia resulting from the proteolytic action of the colon bacilli.

15. **Measles.**—A further examination of measles patients has confirmed Lucas in the belief that there is an early change in the blood picture which may be taken as the first evidence of the infection. This consists in a change from the ordinary lymphocytic predominance which exists normally in infants' blood, to a relative increase in the percentage count of the neutrophilic type of cell. Though there is an actual diminution, here also the diminution in the lymphocytes far exceeds that of the neutrophils, so that there is a complete reversal of the blood picture. The normal percentage of lymphocytes in infants' blood ranges from about 55 to 70 per cent. of the white blood-cells; whereas the neutrophils range from about 25 to 30 per cent., the large mononuclear cells ranging from about 8 to 15. The earliest sign which appears in the blood of an infant coming down with measles is a beginning reversal of this picture. The reversal usually begins about a week before any visible symptoms of infection occur. The actual reversal has occurred at least forty-eight hours before the earliest signs are visible, that is, Koplik spots, coryza or coughing. There is also a definite constant leukopenia present which sometimes appears eight days before the physical signs. and sometimes appears simultaneously with the physical signs. For this reason it is not so reliable a diagnostic method as the cell picture, which is far more constant and reliable as a determining factor in making an early diagnosis.

There also appears an ever increasing number of disintegrated cells, which first make their appearance about the time the cell picture begins to change. These disintegrated cells may not be specific, and probably are not specific in measles; but with the reversal of the blood picture, they are to be counted as a definite factor in the early diagnosis. They appear to be in many instances large, swollen cells, with protoplasm breaking up, and the nucleus, as it were, waterlogged or breaking up into fragments. The shape varies from round to oval, with no sharply defined outline. Granulations are abundant, and they can be seen separating from the nuclei.

19 Case of Long-Standing Amebic Abscess of Liver and Lung. A. Eustis, New Orleans.

16. **Human Trypanosomiasis.**—The patient was seen by Chatard and Guthrie during a relapse, when he presented practically the same symptoms as in his initial attack. The most pronounced symptom was depression, which was in marked contrast to the euphoric state present for a time after the administration of salvarsan. It is interesting that three of the signs most commonly present were absent in this case, namely, auto-agglutination of the red blood-cells, circinate erythema and deep hyperesthesia (Kerandel's sign). The findings on examination of the blood, cerebrospinal fluid and gland juice, as confirmed by the results of animal inoculation, are in accord with the observations of Todd and others as to the relative value of these diagnostic methods. The case is instructive in that treatment for nineteen weeks in the early stage of the infection sufficed to render the patient

practically, or entirely, free from symptoms referable to the disease over a period of three years, but at the end of that time there was a relapse. The improvement apparent after a single dose of salvarsan was very striking. The fact that trypanosomes could not be demonstrated in the patient's blood, even by inoculation of susceptible animals, made Chatard and Guthrie feel that the danger from this source was minimal. Practically, the experience with imported cases elsewhere has shown that the disease is self-limited in the absence of the intermediate host.

30 *Early History of Care and Treatment of Cripples.* D. C. McMurtrie, New York.

26. **Intestinal Obstruction.**—Davis claims that the duodenal and upper jejunal mucosa, unaided by bacterial action, and in *conditions not far removed from normal, can produce a highly* toxic substance, and that although phenolsulphonephthalein is readily absorbed by the normal mucosa of the small intestine, this toxic substance is not. In closed loops one deals with a mucosa which displayes nothing more than a slight hyperemia, sometimes not even that. Injuries from handling are negligible, and absence of normal secretions from above is readily excluded as a cause of the mischief. Loop contents themselves in concentrated form will not stimulate absorption of toxin from the lumen in a freshly made loop. It seems clear, then, that some condition existing in closed loops causes slight but important functional changes in the mucosa, resulting in fatal toxemia. In obstruction and closed loops, a subtle change takes place in the mucosa—nothing is seen with the microscope, yet the cells in some manner discharge, or allow to be discharged, the fatal toxin into the blood. Davis has found it impossible up to the present to demonstrate any increased permeability of the mucosa to the toxic substance.

27. **Natural Immunity of Animals against Poison of Intestinal Obstruction.**—To Davis and Morgan, their experiments remain rather inconclusive. But, they state, it is safe to say that closed loop toxin cannot readily be neutralized by autolysates of normal cat organs, as it can by autolysates of immune dog organs. They advise that great care must be exercised in interpreting the results obtained by introducing supposedly toxic intestinal material into animals of various species. Cats will survive two to six days after the production of closed duodenal loops, often dying of peritonitis. The contents of these loops after heating and filtration, will kill dogs, when injected intravenously, with the same symptoms and anatomic picture seen when dog loop contents are used. Cats are resistant to this toxic material, withstanding with ease doses of over twice as much per gram of body weight, as is necessary to kill dogs. Efforts to neutralize the toxin of duodenal loop contents by incubation with cat organ extracts, cat blood and cat serum, have been unsuccessful. Rabbits and guinea-pigs are much less suitable for testing the toxicity of intestinal fluids than dogs, owing to their great susceptibility to hurtful influences of all sorts. Cats are also less suitable for the same purpose than dogs owing to their high natural immunity against closed loop toxin.

38. **Fatigue and Growth.**—The authors found that extracts prepared from fatigued muscles produce no change in the division rate of Paramecium as compared with that obtained with extracts of normal muscles. Inasmuch as it has been demonstrated that paramecia are capable of detecting chemical changes, for example, in nephritis and in carcinoma, they believe it is justifiable to conclude that the character of the chemical changes occurring in fatigued muscle must differ only slightly from the normal.

39. **Cholesterol Content of Cancers in Rats.**—The strain of cancer used by Bennett was the Flexner-Jobling rat carcinoma. The cholesterol was not injected into the cancers, but was placed subcutaneously in the other side of the animals. Each rat received, repeatedly, 1 c.c. of a 2 per cent. solution of cholesterol in sodium oleate. Nine or ten injections were made during a period of about three weeks. It was soon found that a direct comparison between the injected and uninjected rats was impossible owing to the fact that there was considerable individual variation among those treated exactly alike.

The following deductions, however, seem to Bennett to be indicated by the findings: (1) The injection of cholesterol into rats does not very markedly affect the cholesterol content per gram of cancer tissue. (2) The cholesterol content of cancers increases with the age of the cancers, a fact of some interest when it is remembered that Wacker found the same thing true for normal tissues. (3) The outside, or actively growing part of the cancer, contains less cholesterol than the central portion. (4) If two cancers are of the same age, that one which is very markedly the smaller is apt to contain more cholesterol per gram of tissue, probably because it contains much less actively growing tissue.

40. **Determination of Creatin in Muscle.**—The method proposed by Baumann is carried out as follows: 50 gm. of hashed muscle are weighed into a round-bottom, short-necked Jena flask; to this 125 c.c. of fifth-normal sulphuric acid, and a few chips of unglazed porcelain are added and the whole boiled for three hours under a reflux condenser. At the end of this time the muscle is disintegrated. The solution is now filtered quantitatively through a 15-cm. filter paper into a 250-c.c. volumetric flask, the residue (less than 2 grains of dry material) is washed thoroughly with distilled water, the fluid is cooled and the flask filled to the mark. Twenty cubic centimeters of the claret-colored extract are

pipetted into a small porcelain dish (8.5 cm. in diameter) and 18 c.c. of 10 per cent. sodium hydrate are added while stirring. The partially neutralized fluid is then evaporated on the water bath to about 10 c.c. and transferred quantitatively to a 50-c.c. volumetric flask containing 30 c.c. of saturated aqueous picric-acid solution (the solid particles adhering to the sides of the dish are of no consequence provided the washing has been thorough). The flask is filled to the mark with distilled water when its contents have reached the proper temperature, shaken vigorously, then filtered through a dry filter-paper.

To 25 c.c. of the clear filtrate 6 c.c. of the 10 per cent. sodium hydrate are added and the creatinin determined colorimetrically according to Folin, allowing ten minutes for the color to develop. The standard is a creatinin solution containing about 7 mg. of creatinin per 10 c.c. of solution. It may easily be prepared by heating pure anhydrous creatin (about 80 mg.) with 50 c.c. of fifth-normal sulphuric acid for three hours under a reflux condenser, then diluting at once in a volumetric flask to 100 c.c. The titer of this solution remains constant for months.

42. **Iodin and Phosphorus Content of Thyroid.**—While female animals contain more thyroid tissue and iodin in thyroid combination per unit of body weight than male animals, Fenger says that there is no apparent difference in size and physiologic activity between glands from pregnant and non-pregnant female animals, and the increased iodin metabolism of the fetal glands, both male and female, seems therefore to be independent of the maternal glands, having in common only the source of the iodin. Castrated males contain less thyroid tissue than either uncastrated males or females, but the iodin content per unit of body weight is about half way between the uncastrated male and female animals. The phosphorus content of the thyroid seems to be fairly uniform in all four cases and should only be considered an indication of normal physiologic activity. The garlic-like odor observed in all four lots of glands is due directly to the comparatively large amounts of iodin present and furnishes evidence of a chemical reaction specific to the thyroid and resulting in an organic complex possessing the characteristic odor of oxidizing phosphorus. The odor was observed before the death of the animals, indicating that the reaction actually takes place during life.

56. **Adult Mammalian Tissue in Simple Plasma.**—The total number of cultures made by Walton in the present investigation was 147. Of these 115 showed growth in the first culture, the remainder probably having died owing to some technical error, as they were mostly isolated specimens in a series of six made from the same tissue and under identical conditions. Of thyroid 13 cultures were made, being taken in groups of 6, 3 and 4 from different animals on different dates. Of these 13 cultures only 9 grew, but these when subcultured continued to grow until the third or fourth generation. The specimens from the first animal grew well until the tenth generation, but after this they died suddenly. Of spleen, 68 cultures were made from 12 different animals, being taken in 10 groups of 6 each, 2 groups of 3 and 1 of 2. In all cases growth was present in the first culture, the growing cells being mainly round and wandering cells. After the first transference 34 only showed signs of growth. Of the 43 resulting cultures of the third generation 18 alone showed growth.

In the fourth generation only four pieces of tissue showed evidence of growth, and in all cases this was very slight. Of testicle, 18 cultures were made. Growth occurred in 14 in the first culture. In the second generation the cells grew well and as usual more rapidly and extensively than in the first culture. For the third culture growth had become so marked that seven pieces were divided into two, resulting in 16 cultures of the third generation. Of these only 8 grew, but they showed extensive and rapid outgrowth of cells.

Of kidney 32 cultures were made. Of these only 15 showed growth in the first culture. In the second generation 11 showed growth. The 11 growing tissues were subcultured, but growth took place only in 3. In no case was growth obtained in the fourth generation. Of liver 14 cultures were made. In 9 of these there was active growth. In the second generation evidence of commencing growth was seen in three specimens after twenty-four hours. In the other 6 there was no evidence of growth. In 1 case only in the 3 specimens of the third generation was any growth observed, and this was only slight.

57. **Intestinal Obstruction.**—The series of experiments reported by the authors, they believe, provided conclusive evidence that a definite intoxication occurs in animals with closed loops, and that the intoxication is due to absorption of the loop poison. There are good reasons for believing that the intoxication seen in cats and dogs with intestinal loops and in human intestinal obstruction is due to the same poison or a similar one. It is noteworthy that a dog recovering from simple obstruction showed little evidence of intoxication when a closed duodenal loop was established.

Other evidence will be brought forward later by the authors to show that dogs with simple intestinal obstruction begin to acquire a certain immunity to the intoxication which will protect them against a closed-loop intoxication or the intravenous injection of duodenal loop fluid. They hold that the poison is elaborated by the mucosa, for when the mucosa is destroyed no poison is formed. They feel that their experiments give adequate basis for the belief that intoxication is the essential factor in intestinal obstruction or in the closed duodenal loop complex, and that the intoxication in the two conditions is similar if not identical, and the perverted activity of the mucosa, not an anatomic injury, is responsible for the formation of the poison. The cells and organ extracts of immunized animals can destroy the duodenal loop poison which is so resistant to simple digestion. The destruction *in vitro* during autolysis is quite rapid and the resultant material is non-toxic.

The possibility that this immune tissue juice might be potent when given intravenously at once suggests itself. The authors admit that it is possible that the immune organ extract may destroy the poison *in vivo* and help to tide the animal over a period of acute intoxication. This point is being investigated at present.

60. **Function of Spleen in Experimental Infection.**—Infection of rats and mice with *Bacillus tuberculosis* (bovine type) Lewis and Margot found develops a splenic tumor as a typical lesion. Removal of the spleen from mice (albino) greatly increases their resistance to the infection. This increased resistance cannot be explained at present. The infection in the splenectomized mice tends to remain localized as contrasted

with an almost septicemic type of disease which is usual in the normal animal. The animals of each group that live more than thirty days are apt to present typical exudative lesions. The removal of the spleen does not therefore grossly change what may be called the capacity of the body for exudation.

62. **Etiology of Epidemic Poliomyelitis.**—The globoid bodies, or minute micro-organisms, cultivated from the central nervous organs of human beings and monkeys that have succumbed to poliomyelitis, were detected by Amoss in the incubated brain tissues of infected monkeys in forms indicating post-mortem multiplication. He found that incubating the poliomyelitic tissues in kidney-ascitic fluid culture medium and then crushing them is a more certain method for obtaining cultures of the organism. Identical bodies have been detected by him in blood-films prepared on the twelfth day of the acute attack, from a paralyzed poliomyelitic monkey inoculated intraspinously. The same organism has been cultivated from the blood of a monkey that had received intravenously a large dose of a Berkefeld filtrate of poliomyelitic virus. No other micro-organisms were detected either in the sections of the brain or in film preparations of the blood. These observations tend therefore to confirm the etiologic relationship between the minute micro-organism and epidemic poliomyelitis suggested by the successful cultivation and inoculation experiments reported by Flexner and Noguchi.

63. **Intraspinous Infection in Experimental Poliomyelitis.**—By intraspinous injections of specimens of poliomyelitic virus of suitable virulence, Clark and Amoss cause infection regularly in *Macacus rhesus* monkeys. The virus passes from the subarachnoid spaces into the nervous tissues, in which it multiplies, and into the blood. The constant involvement of the pia-arachnoid membranes in poliomyelitis, even when no paralysis occurs, and the fact that infection can readily be produced by intraspinous inoculation, suggests anew that in the pathogenesis of poliomyelitis the interstitial tissue changes within the meninges, blood-vessels, and ground substance play a determining part. While the virus injected into the subarachnoid spaces can be demonstrated there by inoculation tests forty-eight hours after the injection, it can no longer be detected on the sixth day, at a time when the first symptoms of infection make their appearance. The failure of the cerebrospinal fluid from human and experimental cases of poliomyelitis to produce the disease when inoculated into monkeys is due to the fact that the virus is either fixed by the nervous tissues or passes into the blood.

71 Histopathology of Fordyce's Disease. R. L. Sutton, Kansas City.
72 Differentiation of Streptococci; Preliminary Notes. C. Floyd and S. B. Wolbach, Boston.

65. **Experimental Anaphylaxis in Labor.**—In Kolmer's experiments labor in pregnant guinea-pigs at or near term was not influenced by the intravenous injection of relatively large doses of maternal pig serums collected just before and just after labor; nor by the injection of serums from young pigs removed at term by abdominal section and immediately after normal birth; nor by placental extracts and human placental serum. Subcutaneous administration of placental serum to eight pregnant women near term was without any effect on the uterus and with none or very slight effect on temperature, pulse and respiration. The theory of Heide regarding gradual sensitization of the mother by fetal toxins with onset of labor due to sudden intoxication with a large dose of fetal antigen and thus considering labor an anaphylactic process is not supported by experiments.

67. **Malignant Rhabdomyoma.**—Burgess' case is of interest in that it is evidence that the striated muscle-cell can give rise to tumors of extreme malignancy, which grow with great rapidity, metastasize generally and produce death in a comparatively short time. Another point of interest to which Burgess calls attention is the resemblance of the clinical and anatomic findings to those in cases of rapidly growing myeloblastoma (which are ordinarily known, in which they show a green coloration, as chloroma). The relatively high percentage of myeloblasts and myelocytes in the blood examined during life makes this resemblance especially striking. This appearance of myelocytes in the blood is apparently due to the general invasion of the bone marrow by the tumor, and is associated with the production of myeloblasts in the spleen. A third point worthy of attention is the fact that only after a very extended search was it possible to find tumor cells which had reached a sufficient degree of differentiation to enable them to be recognized as striated muscle-cells. This suggests the probability that many similar tumors pass unrecognized and that a certain proportion of those malignant neoplasms composed of rapidly growing undifferentiated cells, which are ordinarily called sarcoma or alveolar sarcoma by the pathologist, may in truth be malignant rhabdomyomas.

68. **Estimates of Cholesterol in Serum.**—Colorimetric and gravimetric determinations were made by Weston of (1) pure cholesterol, (2) impure cholesterol extracted from serum, and (3) impure cholesterol extracted from serum plus a known quantity of pure cholesterol. Known quantities of pure cholesterol subjected to the same process as that employed in the extraction of cholesterol from serum yielded 99.44 per cent. according to the colorimetric estimates and 108.56 per cent. by weight. Serum to which one milligram of pure cholesterol had been added to each cubic centimeter yielded an excess of one milligram per cubic centimeter according to the colorimetric method and an excess of 1.3835 milligrams by weight. In the seventeen experiments in which a known quantity of cholesterol was estimated by both methods the results obtained by colorimetric estimation were uniformly more accurate than the results obtained by weight.

69. **Giant-Cell Endothelioma of Gums.**—Myeloid or giant-cell sarcomas are divided by Whitman into two groups. The new group consists of tumors very closely resembling the true myeloid sarcoma, but which are clearly of endothelial origin. The giant-cell of this tumor is or may be an intravascular formation. Analogous processes of giant-cell formation occur in blastomycosis and in tuberculosis.

75 Trachoma. C. L. Zugg, Kansas City.
76 Relation of Pharyngeal Lymphoid Ring to General Health. H. C. Markham, Parsons.

74. **Epilepsy.**—Attention is called by Perry to a few points concerning the treatment of epilepsy noted from personal observation and experience. He says, that to be effective, systematic treatment should be begun early in the course of the disease and must be long continued. There are few diseases in which individual treatment is so important. Every case of epilepsy presents distinctive features which have a bearing on its proper and scientific handling. A very large number of patients will show temporary improvement under a change of treatment. In all head injuries a careful examination should be made for fractures of the skull and for evidence of depressed bone or meningeal hemorrhage. Any of these conditions calls for immediate operation as a prophylactic measure. All cases of jacksonian epilepsy should be operated on if seen early.

In long-standing due to cortical irritation and in chronic epilepsy from other causes little may be expected from intracranial surgery. As a routine measure, Perry says a search should be made for peripheral irritations to the nervous system and if any are found appropriate remedies either surgical or medical should be instituted for their relief. The attention should not be too strongly concentrated on merely checking the convulsive attacks, but it should be borne in mind that they are only symptoms of a general nervous disease.

There is no drug which of itself will effect a cure. Of all the drugs used in the treatment of epilepsy the bromin preparations are the most effective. The bromid of sodium is the most satisfactory as a usual thing. There is no advantage to be gained by combining a number of the bromids. Comparatively small doses of bromids usually yield better results on the disease as a whole than do large ones. Perry states emphatically that bromids should never be given except in proper doses determined for the individual case and where the patient is under the frequent observation of a physician. He is convinced that most of the disrepute into which the bromids have fallen in recent years is directly due to their indiscriminate and unscientific administration. Any form of medical treatment will be limited in its effectiveness unless reinforced by hygienic and dietetic regulations.

94. **Operations for Nose Deformities.**—The bridge-splint used by Carter consists of a lightly constructed steel bridge, the two wings of which are hinged together in the middle, and the distance to which they can be separated is regulated by a thumb-screw. The edges of these wings are padded with rubber. The second part of the instrument consists of two small intranasal splints perforated by several small holes. Silk sutures are first passed through holes in the intranasal splints and knotted. By means of a curved needle each suture is then passed from within the nose through the roof fairly near the junction of the bony with the cartilaginous dorsum. The bridge is then placed over the nose and the correct amount of pressure applied to the base of the nasal arch by means of the thumb-screw adjustment. The sutures are then passed through corresponding holes in the bridge and sufficient tension applied to pull the nose up into its proper position. The sutures are then tied together over the hinge of the bridge.

The instrument is said to exert its force along lines diametrically opposed to those of the force that produced the deformity. Carter has found this instrument most useful in treating recent fractures, in correcting lateral displacements, depressed and irregular deformities. This method is said to have the great advantage of correcting the intranasal as well as the external deformity. He has frequently used the bridge-splint in connection with the bone transplantation operation where there was need for additional support.

109. **Vaselin as Substitute for Beck's Paste.**—Salatich describes his method as follows: Sterilize the amount necessary in an open vessel, set in your sterilizer or water bath, then draw into one or more ordinary glass syringes and use partly warm or cool, as we do Beck's paste. In the most foul and freely suppurating cavities, after one injection and without any other treatment, all odor and suppuration diminish. Abdominal wounds, that suppurate either from infection or contaminated catgut, often show very foul pus. After making an incision—only a small one is necessary when vaselin is used—all the pus is pressed out; the cavity is then filled with vaselin, and the wound needs no dressing for two or three days, at the end of which time very little odor and pus remain. The procedure is then repeated, and the dressing for two or three days, at the end of which time very little odor and pus remain. The procedure is then repeated, and the dressings can remain for a longer period, only wiping the abdomen with alcohol being necessary. It was marvelous to Salatich how rapidly cases healed in which the entire wound above the fascial layers suppurated, and with less danger of hernia resulting.

In all acute and subacute sinuses he says it is best to wait until little serum or sero-pus exudes before injecting the vaselin, especially if there is any fear of dead bone at the bottom, which must be removed, or the patient will be made worse, for the vaselin stops drainage and the pus must find some other means of exit. Salatich points out that vaselin is cheap, easily handled and sterilized and free from danger of poisoning.

7 Small-Pox of Fetus in Fourth Month. C. Hall.

2. **Cancer of Breast.**—In subjecting malignant tumors of the breast to the action of the secondary rays from tin, a large plate (10 in. by 8 in.) is used by Roberts and placed close against the breast. By using a plate of this size, the rays are distributed over areas where possibly undetected infiltration may be present, and as these rays have no injurious action on the normal tissues, Roberts considers it advisable to assume the presence of permeation or infiltration in the surrounding area. The exposures should be given for ten minutes each at least, or longer, as the operator considers necessary. The patient need not be exposed during the sitting, but corsets should not be worn. Roberts cites three cases.

British Medical Journal, London

8 *Chronic Intestinal Stasis: "Auto-Intoxication" and Subinfection. J. G. Adami.
9 *Idem: Anatomy and Treatment. S. S. Pringle.
10 Idem: Etiology and Treatment. H. M. W. Gray.
11 Some Effects of Chronic Intestinal Stasis on Female Generative Organs. H. Chapple.

8. **Auto-Intoxication and Subinfection.**—Adami believes that it is more rational to regard the evil effects of intestinal stasis as, in the main, a result of conditions favoring subinfection and low forms of infection than as a result of chronic intoxication. The term "gastro-intestinal auto-intoxication" is pernicious and not to be employed by any self-respecting member of the profession, save for so limited a set of conditions that for ordinary purposes it may safely be expunged from the medical vocabulary. While he regards it as being possible that the symptoms and diseases enumerated by Lane may follow intestinal stasis, he is convinced at least a large proportion of them may originate independently of such stasis. Before recommending the operation of short-circuiting it is necessary, therefore, to make the fullest studies, so as to discover, if possible, the nature of the organism responsible for the disturbance and its probable seat of entry. A discovery of the cause of the symptoms is calculated to suggest the appropriate means of treatment by means other than short-circuiting. Only when these have been tried and found wanting is removal or short-circuiting of the colon justifiable.

9. **Chronic Intestinal Stasis.**—Pringle divides the treatment of chronic intestinal stasis into (1) prophylactic, (2) medical, (3) local operative, (4) radical operative. He advises under these heads the proper development of the abdominal muscles by suitable exercises; the acquiring in early life of a regular habit of *emptying the bowels and the avoidance of the routine* use of aperients; the use of an abdominal belt, and the internal administration of paraffin in doses of 1 to 4 drams, three times a day, in the form of liquid paraffin (B. P.) flavored with one of the essential oils, such as cinnamon or peppermint.

In midline ptosis he, as a rule, performs Rovsing's gastropexy, together with shortening of the gastrohepatic and gastrocolic omenta, but in some cases he has employed Coffey's omentopexy. If the liver has also prolapsed and would endanger the success of the gastropexy, he first fixes it up by shortening the falciform ligament and suturing the free edge of the liver to the anterior parietal peritoneum. If the upper abdomen is very contracted he has enlarged it after the manner advocated by Coffey and Rovsing. Should the splenic flexure be slung very high, he divides the costo-colic ligament and opens up the angle by suturing the descending colon to the left lateral abdominal wall after dividing any adhesions which might bind the two limbs of the angle together.

In kinking at the duodeno-jejunal junction he fixes the jejenum to the under-surface of the transverse mesocolon in such a way as to open out the angle; in other words, he reproduces the mesocolic band. For Lane's ileal kink he divides the band parallel to the line of the bowel and sutures the resultant rent vertically, employing, if necessary, an omental graft to assist in covering in the raw area. In mobile dilated cecum unassociated with Jackson's membrane he has employed many methods of fixation, and has also enfolded it in cases of marked dilatation. Recently, however, he has used the method of Coffey. If a mobile cecum is associated with Jackson's membrane, he divides this prior to fixation. When Jackson's membrane is found without ptosis of the cecum, but constricting the colon, he merely divides the membrane, and if any raw surface is left, which occurs in cases of secondary inflammatory thickening, he uses an omental graft to prevent adhesion formation.

If a double-barrelled colon be present, or if the bands in the neighborhood of the hepatic flexure are very dense, and likely to recur, Pringle does a lateral anastomosis between the cecum and the transverse colon, or—and he thinks this the better procedure—excises the cecum, ascending and right half of the transverse colon, and restores the continuity of the intestine by implanting the end of the ileum into the remaining part of the transverse colon. In all cases of trouble in the cecal region he also removes the appendix. Where the last or sigmoid kink is causing trouble he divides the shortened leaf of the mesentery transversely and sutures it vertically. The radical procedures Pringle reserves, short-circuiting and colectomy, for the cases in which multiple conservative operations would not be effective, or in which the length of time necessary for their performance would endanger the life of the patient. His opinion is that ileocolostomy is not a good surgical procedure, and he believes that where conservative operations are contra-indicated the best operation is complete colectomy.

21 Case of "Pre-Eclampsia" at Twenty-Fourth Week; Cesarean Section. V. Bonney.

16. **Serum Reaction in Pregnancy.**—The serum of pregnancy and malignant disease was tested by King against various tissues. The albumin was obtained from the urine of a patient suffering from albuminuria of pregnancy, and her serum was the only one out of four pregnant patients which did not digest this substance. The carcinoma tissue was obtained from a case of advanced carcinoma of the cervix, and both this and the albumin were prepared exactly in the same way as the placental albumin. Out of nine pregnant serums, six digested other albumins besides placenta, thus demonstrating that the ferments of pregnancy are not limited in their power of digesting albumin. Of eight cases of malignant disease, three digested placental tissue. These three cases included one of sarcoma of the knee. The digestion of the placenta shows that a ferment was present, and rather suggests to King that a positive result might have been obtained if suitable tissue had been available. Urinary albumin was not, however, digested by this serum, though a case of epithelioma of the tongue reacted strongly to it. Three sarcomas were negative to carcinoma tissue. Thus out of seventeen cases of pregnancy and malignant disease, nine serums digested albumins of a different type from that against which, *ex hypothesi*, they were produced. Hence if King's observations are accurate the ferments are not specific.

22 *Use of Tuning-Fork in Diagnosing Outlines of Solid and Hollow Viscera of Chest and Abdomen and of Certain Pathologic Conditions. J. Cantlie.
23 "Espasmo Tropical"; Malignant Disease Associated with Parasite in Blood. R. Vergne.
24 Detection of Trypanosomes in Animals. A. Lundie.

22. **Diagnosing Outlines of Solid and Hollow Viscera of Chest and Abdomen.**—For some years Cantlie has used the tuning-fork in conjunction with the stethoscope as a means of ascertaining the exact outlines of the liver and other organs. The principle involved in the use of the tuning-fork-stethoscope method is that when the stethoscope is placed over an organ, be it a solid organ such as the liver, spleen, heart, etc., or a hollow organ such as the stomach or cecum, and the vibrating tuning-fork is made to impinge on the surface of the body over one or other of these organs, the note of the tuning-fork manifests by its loudness the limits of the organ being examined, and the moment the limits are passed the note becomes faint, distant, or is altogether inaudible. The best results are obtained by a fork whose note is G-sharp, and the end of the fork is not flattened, but pointed rather. The fork may be struck against anything hard, the heel of the boot if nothing else is available, and while loudly vibrating the end of the stem is pressed lightly but firmly on the skin. The practical application of the tuning-fork-stethoscope method, applied, say, to the liver, is as follows: Place the stethoscope (binaural) on the lower part of the chest wall just above the lower part of the right true rib cartilages about one inch behind a line drawn downward from the right nipple. The tuning-fork is now made to travel from the region of the chest midway between the sternum and the nipple line downward over the liver. The note heard (if heard at all) when the tuning-fork is over the lung is faint or distant, but the moment it reaches the area of the liver the note is loudly heard; when the lower limit of the liver is reached and the tuning-fork has other abdominal organs beneath it, the sound suddenly fades away to a faintly distant hum. The degree of pressure necessary for diagnostic purposes varies; over the chest the end of the fork has only to be gently pressed against the skin; but when a careful search has to be made for the limits of the lower edge of the liver, as in stout people or in cases of distentions from gas in the intestines or fluid in the peritoneal cavity, the fork has to be pressed fairly deeply at times, so that the piece of intestine may be pushed aside or the fluid between the abdominal wall and the liver displaced.

28 *Protein Metabolism During Starvation and after Administration of Milk Protein. G. Mann.
29 *Toleration of Arsenic by Human System. H. G. A. Harding.

28. **Protein Metabolism during Starvation.**—Starvation, according to Mann, invariably leads to a rarefaction of the cell body and its processes. In all starved animals the contractile elements of the heart, both the isotropous and the anisotropous, undergo an atrophy amounting to 25 per cent. of the normal state. The nervous system also suffers during starvation. This loss, if stimulation of the nervous system is eliminated, is restricted to the conducting paths. Feeding with sodium caseinogenate containing 5 per cent. of sodium glycerophosphate it is possible within two hours to get a definite increase in the nuclear activity even of cells which are not supplied directly by the blood, as, for example, in the cornea and in cartilage. This milk protein further leads to an increased depth of staining of the heart muscle and of nerve fibers, and this deeper staining it is impossible to explain in any other way, except to assume that the amino-acids liberated by the digestion of the caseinogen are actually built up into what Mann terms the "available" protein. From the conservation of protein point of view, as well as from that of restoration, it is absolutely necessary to have a nonpurin-containing, easily digestible albumin. From the evolutionary point of view milk protein is the best. Caseinogen with its phosphorus content and other radicals is to the mammal what the yolk and the white of egg together are to the fowl. Neither of these foods contains purin, but, being mammals, Mann advises to give milk protein in fevers and in all cases of debility in preference to eggs, especially as erepsin by itself is capable of digesting caseinogen. Also, he says, give a minimal amount of the fats of milk, just sufficient to bring calories up to 3,500 or 4,000, especially when dealing with adults, and thereby hasten absorption of the amino-acids and also the liberation of waste nitrogen by the liver. Milk sugar, because of its slow conversion into its monosaccharids, and therefore steady supply of potential heat, should be left for calorific purposes in combination with caseinogen.

29. **Toleration of Arsenic by Human System.**—Beginning with $\frac{1}{60}$ gr. doses of arsenious oxid thrice daily immediately after food, Harding reached the dose of $1\frac{1}{6}$ gr., which produced irritability and distinct and lasting discomfort every way it was taken and all precautions notwithstanding. In 1 gr. doses the drug could only be taken with comfort if dry foodstuffs were consumed at meals—if liquid beverages were

partaken of, or if the food was of the sloppy order, the administration of the grain dose of As_2O_3 produced immediate discomfort and burning pains in the abdomen, lasting forty minutes to one hour and acting as a distinct aperient within three hours.

31 *Reflex Syndrome Started from Large Intestine. (Cas grave de réaction colique.) A. Mathieu.
32 Pathologic Proportion of Amino Acids in the Urine. M. Labbé and H. Bith.

30. **Digestive Lipemia.**—Lemierre and his coworkers comment on the simplicity and convenience of methods of research on the blood rather than on the stool when studying the absorption of substances from the food, especially fat. By determining the fat content of the blood during or following at once on digestion, we can recognize any pathologic increase or drop. Either the ultramicroscope for the whole blood or chemical analysis of the serum will supply the figures. The blood of a person fasting for twenty-four hours shows none of the fat granules in the spaces between the corpuscles on dark field illumination, but after a meal with much fat the blood swarms with the shiny granules of fat. Nothing should be eaten after a light supper, without fat, until a drop of blood is taken next morning to examine with the dark field. Then the test breakfast is eaten and the blood is examined anew from two to five hours afterward when the fat particles in the blood are at their maximum. Under normal conditions, the blood swarms with them and chemical tests confirm that this blood dust is truly fat particles.

Their research has demonstrated that in case of total obstruction of the biliary passages there is no absorption of fat into the blood. When there is jaundice from retention of bile pigment alone, the absorption is not modified but when there is retention of the bile salts, the fat particles cease to appear in the blood. This dissociation of the bile and retention of only part of its elements have been demonstrated again and again by determination of the digestive lipemia. For this isolated retention of the pigment or of the bile salts alone, the liver itself must be responsible, as nothing else could display such selective action in this line. Experiments on numbers of dogs confirmed these theoretical assumptions, injury of the parenchyma of the liver by means of specific cytotoxins reproducing at will the two types of dissociated jaundice. The pancreas was shut off from the digestive tract in twenty dogs but this did not seem to influence the absorption of fat from the food; this suggests that in many cases of defective absorption of fat in which the pancreas was incriminated, the liver was really at fault.

31. **The Colon Reaction Syndrome.**—Mathieu called attention in 1909 to the severe disturbance, vertigo, syncope and pain which are liable to come on suddenly as a reflex reaction to the abrupt emptying of the large intestine after a period of constipation. Any syncope may prove fatal under certain conditions, and the colon reaction may superpose a puzzling element in other affections, especially in neurasthenics and with chronic colitis or lead poisoning. Gaucher has reported a case of the latter in which the patient died during the act of defecation and nothing except the assumption of this colonic reaction could be found to explain the fatality.

To illustrate the possible gravity of this reaction, Mathieu gives the details of a case in which a young woman was operated on for supposed perforation of a gastric ulcer but nothing of the kind was discovered and the retrospective diagnosis was a series of colonic reactions occurring each time at defecation after a period of constipation. The main symptoms were vomiting, epigastric pain, tendency to collapse, syncope, and small rapid pulse. In another case a woman of 50 with chronic colitis had a very severe colonic reaction following a medicated enema; the pulse kept good but the cold extremities, cyanosis, drawn features, general depression and other features of the crisis persisted for three hours.

36 Legislation on Rest for Parturients. M. Levant.

34. **Prolapse of the Cord.**—Johansson states that this occurred in 35 of the 7,518 obstetric cases at the Lund maternity since 1900. In nearly 29 per cent. of the cases the cause of this complication seemed to be some contraction of the pelvis. In 20 cases there was head presentation, in 6 shoulder, and in the others breech or foot presentation. There was placenta praevia in only 1 case. In 2 cases the fetus was dead and the delivery was left to Nature, but in the other cases it was hastened to save the child. The lesson taught by this material is the necessity for delivering the child at once even if labor has only just commenced. This can be easily done by incising the cervix, which was done in one of the cases with excellent outcome, delivering the fetus before it showed the slightest signs of asphyxia. This is particularly important with breech and foot presentation. Temporizing is more dangerous for the child than instrumental or operative delivery. The experiences at other clinics are compared with those at Lund, to sustain these statements.

45. **Splenectomy for Chronic Jaundice with Splenomegaly.**—Gilbert had a patient drifting into pernicious anemia when he began to read of benefit from splenectomy in such cases, and had soon found records of forty-eight in which splenectomy was applied for progressive anemia. Five of the patients died but all the others were improved and a number were apparently cured. The progressive anemia and emaciation in his patient, a butcher of 45, the absence of pain in the spleen region and the movability of the spleen all encouraged its removal, which was done with the minimum of operative shock. In a week the number of reds had climbed from 1,200,000 to 1,900,000 and the gradual improve-

ment continued until the general condition was very satisfactory. The spleen weighed 950 gm. but seemed normal until histologic examination revealed sclerosis and the traces of intense hemolysis. Although the benefit did not amount to a resurrection, yet the improvement was beyond question and has persisted for over a year to date.

48. **Tonus of the Uterine Cervix as Guide in Treatment of Pelvic Disease.**—Macrez expatiates on the value of the information as to conditions in the pelvis which may be obtained from the uterine cervix — whether it is relaxed or spasmodically contracted. In some cases the atony alternates with hypertonicity. With hypertonicity, the general nervous system requires soothing; electricity or spa treatment is useful here. As long as the sphincter of the internal os is not normal, the cure of a gynecologic affection is not complete and recurrence is liable. There may be some erosion of the mucosa causing the trouble, similar to that from an anal fissure but promptly amenable to treatment. When the cervix is abnormal in this way, the patient may suffer vaguely or may have tenacious neuralgia in the pelvis, or permanent sterility when she is longing for children. If a pregnancy intervenes, the cervix enters on a new phase and all returns to order; some women say they never feel quite well except when they are pregnant.

49. **Typhoid Fever in Diabetics.**—The typhoid fever in the case reported had a number of complications and ran an atypical course for which the diabetes was probably responsible. This experience confirms the general impression that a febrile affection often has an aggravating influence on diabetes. It may even arouse the tendency to diabetes for the first time in a person presumably healthy. The typhoid is liable to run an unusually severe course in a diabetic; of the seven cases of this class he has found on record, only two of the patients survived the typhoid.

55 Operative Treatment of Gastric Ulcer. L. de Rydygier.
56 *Autodrainage for Internal Hydrocephalus. L. M. Pussep.

56. **Operative Treatment of Hydrocephalus.**—Pussep trephines above the ear, and cuts a tongue-shaped flap in the dura 2 cm. in diameter and 3 cm. long, which is slit its entire length. The brain is then punctured with a needle 3 mm. in diameter, made of several small tubes 3 cm. long, screwed together to form one tube. The tube-needle is pushed down into the ventricle until fluid commences to flow. Then the superfluous parts of the tube are unscrewed and the halves of the outer end of the part of the tube left are bent apart at right angles. The two flaps of dura are drawn underneath the little T-tube. It thus rests on the dura flaps, and can rise and fall freely with the respiratory movements of the brain. He has applied this technic to eighteen children for hydrocephalus and to two adults for brain tumors. Among the fourteen children whose case-histories are given in full, in three the hydrocephalus was secondary to a brain tumor, in one acute, and in ten chronic. In the ten chronic cases benefit was constantly realized, the more pronounced the earlier the intervention. In the brain tumor cases the operation warded off blindness. Two of these patients were relieved of their distressing symptoms and vision persisted unimpaired. Necropsy in one case in which the tube had been worn for three months, showed that a permeable passage had been definitely formed. By eliminating the symptoms due to the hydrocephalus, it may first prove possible to locate a brain tumor. Vigorous internal treatment and general measures are indispensable to reenforce the action of the autodrainage. The technic advocated is a modification of Krause's method.

65 Dystocia from Distention of Fetal Bladder. P. Böhl.
66 *Carcinoma at Same Time in Uterus and Adnexa. P. Werner.

59. **Means to Accelerate Labor.**—Tassius says that when it is a question of reenforcing weak labor contractions, the practice at the Breslau maternity is to give quinin and supplement this with hot compresses, hot baths and superheated air. This with primary weakness of the labor contractions at term or with abortion tends to induce vigorous and prolonged labor contractions. During the second stage of labor, when it is a question of hastening delivery with prompt and vigorous action, hypophysis extract is given to make it unnecessary to apply the forceps. Ergot is only exceptionally given at any time except to combat inertia, atony of the uterus and afterhemorrhage. It is generally combined with some hypophysis extract and hot compresses to induce a rapid and persisting effect. When it is a question of inducing labor contractions to bring on premature delivery, the metreurynter (glycerin-sheep bladder) is the sole reliance. The experiences related cover two years and embrace 4,109 deliveries.

62. **Ovulation, Menstruation and Gestation.**—Miller discusses the biology of the corpus luteum and its connection with gestation, his clinical and experimental experience confirming, he thinks, the assumption that the corpus luteum is a periodically developing gland with an internal secretion. It is responsible for the cyclic transformation of the endometrium into decidua, and also for the trophic conditions in the uterus, the turgor which protects the incipient pregnancy; the corpus luteum also prevents the ripening of another ovum while the pregnancy lasts. Menstruation is merely the relief of the hyperemic uterus; it has nothing to do with conception. The most favorable time for conception is the tenth day before the onset of the following menses. The ovulum of the first suppressed menses is the one embedded; there is no such thing, he declares, as a postmenstrual embedding. The standard duration of pregnancy should therefore be reduced by nineteen days.

64. **Influence of Mother's Age on Course of Childbirth.**—Zweifel gives twenty-five charts showing the frequency of complications, operations, etc., in 10,000 maternity cases classified according to ages. The proportion of operations required increased with the mother's age, both for women who have borne children before as well as for the primiparae. This was true also for eclampsia and placenta praevia, but laceration of the perineum occurred less frequently with pluriparae with increasing age and more frequently in older primiparae. The mortality of the children was higher with pluriparae than with primiparae, on account of the greater tendency among the former to transverse presentation and placenta praevia.

66. **Simultaneous Cancer in Uterus and Adnexa.**—Werner was not able to find any clinical data which permit differentiation of this condition. He found a cancer in the adnexa along with the cancer in the uterus in 4 per cent. of 374 operations for cancer on the internal genitals; in three of the fourteen cases the cancers seemed to be entirely independent of each other.

67. **Cleft Palate and Harelip.**—This communication issues from the university clinic at Berlin in charge of Bier and is profusely illustrated; 212 bibliographic references are appended. The early intervention and the Brophy technic are discussed in particular, Kaerger stating his preference for the technic used at the clinic which differs from Brophy's especially in that the alveolar processes are not separated and their position changed. He emphasizes the importance of cooperative supervision, from birth onward, by pediatrist and surgeon, of children with these deformities until they have been finally and completely corrected and approximately normal conditions restored. The surgeon should determine the indications for intervention at the earliest possible moment compatible with the development of the child and its condition as regards nourishment and growth; the various steps of the intervention should be guided according to these indications.

68. **To Promote Healing of Wounds in Parenchymatous Organs.**—After injury, incision or multiple rupture of the liver, spleen or kidney in twenty-two large dogs, the wound healed remarkably promptly and perfectly under a smoothly fitted sheet of fascia tissue with care to aspirate all blood and clots. A water-jet vacuum pump was used to aspirate the blood which it did so effectually that healing was materially promoted, as otherwise there is a tendency to thrombus production after such injuries. The fascia tissue fitted over the traumatized area serves as a living tampon, protecting against secondary hemorrhage, reenforcing sutures and reducing the number of sutures necessary and enabling ligatures to be dispensed with. This is a special advantage in operating on the liver as intrahepatic and analogous ligatures induce a tendency to necrosis. The superficial fascia is convenient for the purpose, and it does not irritate the organ in any way so that there is no disposition to proliferation of connective tissue in response. The fascia can be slit, the kidney drawn through it and the fascia then drawn together below to make a kind of capsule pressing tight on the kidney surface and arresting hemorrhage while coaptating the lips of jagged rupture wounds so that healing proceeds perfectly; all blood and clots are first pumped out with the vacuum pump. The fascia is elastic enough so that no pressure necrosis results, even when it is drawn quite tight, and there is no development later of a cicatricial capsule to entail contracted kidney.

69. **Nail Extension in Treatment of Fracture.**—Riedl applied nail extension in forty cases of fracture of the femur, tibia or calcaneus, and regards the method as almost indispensable in the treatment of serious fracture. It requires constant Roentgen control and should not be applied near discharging wounds.

70. **Sterility of the Bile.**—Toida's research indicates that the bile is sterile under normal conditions but it is a good culture medium for the colon bacillus, enhancing its virulence, while it is an unfavorable medium for the growth of the streptococcus and the pneumonia diplococcus.

73. **Acute Pressure on the Brain.**—In this part of his monograph Breslauer reviews the testimony on hand as to the cause of the unconsciousness with concussion of the brain, and draws the conclusion that it is not the general shake-up of the brain which is responsible for the symptoms with concussion of the brain. Both the clinical and experimental data point to a local injury of the base of the lower part of the brain stem. The general phenomena accompanying concussion of the brain are consequently focal symptoms.

75. **Stenosis of the Biliary Passages without Cancer or Gall-Stones.**—In the three cases reported an operation was done, but if the character of the trouble had been known beforehand, medical-dietetic measures would probably have answered all the indications and proved fully as successful in curing the disturbances. Although such cases are rare, yet they present such a characteristic clinical picture that differentiation is generally possible; the patients have suffered for many years, possibly even from childhood or youth, from intermittent attacks of apparently gall-stone colic without fever, with or without transient jaundice, and without any appreciable influence on the general health, but often with an unmistakable connection with gastro-intestinal disturbances. The cases are usually interpreted as chronic cholecystitis, and the gall-bladder is removed, but the attacks of colic are liable to recur later. The inflammation in the biliary passage probably responsible for the trouble may be secondary to gall-bladder disease, or the gall-bladder trouble may be secondary.

One of the cases reported shows that when the latter is the case, there is no sense in removing the gall-bladder which is only secondarily affected. In his case the colics persisted unmodified and each was preceded and followed by transient jaundice without fever. There is much to sustain the assumption, Berg thinks, that the aggravation which followed the removal of the gall-bladder was due to the loss of the assistance previously furnshed by the contractions of the gall-bladder in the work of cleaning out the stenosis from accumulations of pigment and mucus, etc. In every such case the question should be debated whether the removal of the gall-bladder does in fact represent the elimination of the most important source of the irritation. If the gall-bladder is of comparatively sound aspect and if it contains stones, it had better be left intact and merely the stones removed.

It is useless to drain the gall-bladder or the hepatic duct in these cases, while it is liable to entail severe infection. The laparotomy therefore should be exploratory, examining the bile, the gall-bladder, the hilus of the liver, the duodenum and the pancreas. Weighing the findings in connection with the history of the case will be the guide to treatment which should be conservative-surgical. Dieting and care of the stomach and duodenum are the most important measures for curing the morbid tendency. The non-malignant stenosis in question is liable to modify the chemical composition of the bile to such an extent as to lead to production of concrements in the gall-ladder or even in the liver.

76. **Prostatectomy.**—Grinenko insists that the prostate has no capsule of its own and that there is no anatomic justification for speaking of it as separated into lobes. He regards the transvesical operation as the only rational method; this removes the peri-urethral adenoma causing the trouble while the prostate proper is left approximately intact.

89 *Diagnostic Puncture of the Brain. (Die Neisser-Pollack-sche Hirnpunktion.) E. Röper.
90 *The Spleen Function. (Milzfunktion.) A. Meyer.
91 *Perforated Gastric Ulcer. (Das perforierte Magengeschwür.) J. Schoemaker.
92 *Functional Tests of the Kidney. (Funktionelle Nephritisdiagnostik.) L. Borchardt.

89. **Puncture of the Brain.**—Röper reviews the history, technic and results of puncture as set forth in sixty-one articles in German literature. All agree that it has proved an extremely useful aid in the diagnosis, but the general opinion seems to be also that it should not be attempted outside of well-equipped hospitals. This is particularly necessary as the puncture may indicate the necessity for trephining at once. On account of the fatal prognosis of a brain tumor, the slight danger from the exploratory puncture may well be overlooked. The puncture alone may relieve to such an extent that trephining may not be necessary. Röper concludes his review with the remark that his experience with necropsies impresses on him more and more that puncture of the brain is not applied often enough. The information to be derived from it is naturally of greatest interest for neurologists and internists, and he hopes that they will learn to appreciate its importance better.

90. **Functioning of the Spleen.**—This review embraces 363 articles which are listed by titles. There seems much to sustain the assumption that some substance is produced in the spleen which causes or promotes peristalsis, in addition to its function as the seat of destruction of blood corpuscles.

91. **Perforated Gastric Ulcer.**—The literature since 1902 is listed and reviewed; it shows a total of 748 operative cases of perforated gastric ulcer, with mortality of 357. This is not much of an improvement over the 48 per cent. in the 387 cases compiled by Brunner in 1903. Progress must be along the lines of earlier diagnosis. In 176 recent cases only sixty-nine of the patients were able to have the operation done within the first ten hours; in fifty-one cases there had been an interval of over twenty-five hours. This compilation fits in with Brunner's, so that the two comprise the international literature 1897-1911.

92. **Estimation of Renal Functioning.**—Borchardt recapitulates the result of recent research on the functioning of the kidneys in health and disease, and remarks that the important points recently learned in respect to the renal elements involved in various forms of nephritis render the outlook very promising for further research along the same lines to complete our knowledge of kidney function. Study of the glomerular and of the tubular diuresis, separately, may prove very instructive. The water test may be regarded as giving information in regard to tubular diuresis. With red granular kidney the tubular diuresis seems to be intact, while with secondary contracted kidney and the combination form, tubular diuresis is lacking. With mild nephritis, more urine is voided during the day than at night, as the food has a diuretic action on the sensitive kidneys. With severe tubular disease, the contrary is observed; there is no oversensitiveness of the kidneys and no tubular water diuresis during the day. It is possible that the badly damaged kidney may recuperate to such a degree during the night that this alone would explain the more copious excretion of urine at night. Volhard's test for the concentrating capacity of the kidney reveals whether there is hyposthenuria or not. The Vaquet and Cottet test yields no information in regard to glomerulus functioning, but throws much light on tubule functioning. Borchardt says of the phenolsulphonephthalein test that it does not seem to be applicable to pregnant women; positive findings have been reported in apparently entirely normal persons giving a constantly negative response to other tests. It would be interesting to apply this test in dubious cases of kidney trouble without albuminuria or tube casts, or in cyclic or orthostatic albuminuria. He does not know of any reports of its application in such cases.

94. **Differentiation of Human and Bovine Tubercle Bacilli.**—Schürmann and Buri state that there are about 1,441 cases of human tuberculosis on record in which the bacilli were cultivated with a view to determining whether they were of the human or bovine type. The bovine type was found in 8.1 per cent. of the total, and mixed in 0.5 per cent. The bovine type was found only in children. The present article is the first in Switzerland along these lines, and reports the outcome of bacteriologic study in seventy-five cases of tuberculosis of different organs. The bacilli of both types resemble each other so closely that it is difficult if not impossible to distinguish between them on culture media, but subcutaneous injection of ground tuberculosis tissue into rabbits solves the problem in the most rapid and simplest manner. None of the patients from whom the material was derived was under the age of 16, and in none was the bovine tubercle bacillus discovered.

96. **Somatic Basis for Dementia Praecox.**—Frankhauser comments on the way in which the latest research has demonstrated microscopic changes in the brain with dementia praecox which seem to be the work of abnormal functioning on the part of certain of the ductless glands, especially the thyroid and the genital glands. The blood picture also seems to be modified and possibly also the lymphatic organs. All the newly learned data from serology also confirm the assumption of a somatic basis for the trouble.

98. **General Spasms.**—Grober in commenting on the differentiation of an epileptic seizure from hysteria, says that the former corresponds to changes in a circumscribed portion of the brain and consequently the spasm is restricted to certain movements and the reflexes are liable to be lost. Only exceptionally is the pupil reflex lacking in hysteria and when this occurs, it suggests a possible combination of hysteria and epilepsy. He has had several cases in which the convulsions of hysteria developed in the course of years into true epileptic seizures. The epileptic seizure occurs more suddenly than the hysteric. If the pulse and respiration are good, Grober places the patient on a bed or sofa pushed against the wall, with the backs of chairs against the outer side of the bed, the wall and chairs protected with blankets or cushions so that no physical injury can occur. Then he insists on quiet and expectant treatment, merely striving to rouse the patient by moral suasion. Violent measures such as a box on the ear would rouse the patient, but would destroy his liking for and trust in the physician, which are especially important in the management of hysteria. If the spasm keeps up over an hour, 3 to 5 gm. chloral might be given in an enema.

Nothing will break up an epileptic seizure, and the physician can only watch over the patient in bed, refraining from any interference, allowing the patient to rouse naturally. If the pulse and respiration keep good, the seizure may last for an hour without harm; bromid or chloral might then be given, but never by the mouth. If the seizures keep up for hours, one is justified in cautiously putting the patient under the influence of chloroform or morphin. In toxic convulsions, purges, venesection, sweating procedures, copious drinking of milk or alkaline water, copious and long continued rinsing out of the stomach may be indicated. Lavage of the stomach may ward off further spasms in acute gastro-intestinal catarrhal affections that have brought on tetany or convulsions. Full warm baths for fifteen to forty-five minutes or application of superheated air may prove useful, aborting further spasms by cold packs to head and chest. In tetanus the slightest jar or movement may bring on new convulsions, so that the care of the patient with tetanus is of vital importance. Even the act of swallowing may be dangerous. Many tetanus patients succumb to pneumonia from fluid or food getting into the air passages. Long full warm baths may quiet the patient in mild forms of tetanus, but there is danger of bringing on more spasms as he is moved into the bath. Superheated air baths have done good service in the experience of some. When the muscles of respiration share in the contracture, artificial respiration becomes necessary, but the ordinary procedures are blocked by the rigid contractures and nothing more than cautious rhythmic compression of the lower circumference of the chest can be applied with or without the oxygen tank.

With rabies, any noise, any movement, even of the air, is liable to bring on the spasm. Only the strongest narcotics bring relief here; the maximal dose of morphin may give the patient a few hours' respite. Chloroform increases the agitation; the subcutaneous narcotics are better.

99. **Thrombosis.**—Ribbert thinks that there is great practical importance for the prophylaxis of thrombosis in the results of recent research which indicate that an enhanced tendency to coagulation is responsible for the development of thrombosis. The primary cause seems to be some change in the inner surface of the vessel. Disturbances in the circulation add their share, but the main reason why the thrombus forming under these conditions is not harmlessly dissolved away again is because the blood is abnormally prone to clot, and this tendency to abnormally early and intense coagulation is generally under medicinal control.

100-101. **Further Research on Serodiagnosis.**—Guggenheimer has continued his research on the influencing of fermentative processes by human serum, and has found that while normal serum checks autolysis of organ tissues, the serum in certain pathologic conditions promotes the autolysis of human brain and rabbit liver tissue. Serum from pregnant women behaves like normal serum in this respect, checking autolysis, while placenta extract, on the contrary, promotes autolysis.

Weiss announces that similar tests showed an opposite behavior also on the part of the serum from patients with gastric cancer and normal serum. This renders plausible the assumption that something is lacking from the serum of certain persons and that this lack permits the cells to proliferate unchecked, with cancer as the result, at points exposed to special mechanical stress or irritation. It may be possible, he adds, to isolate from normal serum the element in question, the lack of which permits malignant proliferation of cells, and utilize this element in prophylaxis and treatment of cancer. The work is a preliminary communication from the Tübingen clinic for nervous and mental affections, and experiments are now under way with tissue extracts made from various parts of the stomach, with the aim to differentiate not only the cancer itself, but its very site in the stomach by the protective ferment formed on parenteral injection of the extract in question.

103. **The Graduated Tuberculin Reaction.**—Kögel declares that the Pirquet skin tuberculin test is practically valueless unless it is applied with graduated strengths. For this he commends the Ellerman-Erlandsen tuberculin titer method described in THE JOURNAL, 1909, lii, 1634. To be conclusive it must be applied repeatedly.

106. **Causes of Contracted Kidney.**—Siegel reported in 1908 that acute nephritis had developed in some dogs who stood in cold water for a time. It is a familiar experience that getting the feet wet often starts a "cold," bronchitis or ear affection, or even acute nephritis. Excessive perspiration of the feet keeps them clammy, and Engelen regards this as an important factor in kidney disease. He has found a history of hyperhydrosis pedum in every case of contracted kidney in persons free from arteriosclerosis, gout, syphilis, acute nephritis, lead poisoning, alcoholism and general dissipation. In one instance the apparently primary contracted kidney trouble developed in the forties in a brother and two sisters all of whom always suffered from excessive sweating of the feet. The constantly positive history in his exceptionally wide experience with contracted kidney, suggests the necessity for prophylactic measures, keeping the feet dry, controlling the tendency to excessive sweating by the usual formaldehyd treatment.

Medizinische Klinik, Berlin

January 11, X, No. 2, pp. 47-90

107 Vaccine Therapy in Gonorrhea. C. Bruck.
108 *Early Diagnosis and Modern Treatment of Blood Diseases. (Blutkrankheiten.) H. Hirschfeld.

110 Expulsion of Entire Lining of Esophagus after Drinking Lye; Two Cases; Recovery in One. E. Liebmann.
111 *Dissolving Capacity of the Blood Serum. (Lösungskunst im Serum.) H. Schade.

108. **Treatment of Blood Diseases.**—Hirschfeld says that it is generally possible to find some preparation of iron that the patient can take, but arsenic is useful when the number of blood corpuscles is much below normal and there is little response to iron. Milk contains extremely little iron, so it need not be forced on the anemic as is often done. Small amounts of alcohol have a stimulating action on some anemic patients while others are unable to stand it. There is no deficiency in iron in pernicious anemia, but with repeated courses of arsenic it is possible sometimes to keep patients in good condition for years, even sometimes retaining their earning capacity. The patient should be kept under constant supervision so that the arsenic can be promptly resumed at the first signs of a relapse; iron may then prove useful also when the arsenic fails. In pernicious anemia, hydrochloric acid and pepsin must be given persistently. Transfusion of blood has sometimes done service but never realized a cure.

The reports to date on benzol treatment of leukemia are encouraging on the whole, but extreme caution is necessary, as in some instances the leukocytes dropped below the normal figures and death soon followed. The combination of radiotherapy and benzol seems most promising. It does no good to remove enlarged leukemic lymph-nodes as the trouble is systemic. If they are compressing organs or nerves they can be reduced in size by exposure to the Roentgen rays or radium. The leukemic lymph-node seems to heal faultlessly after an operation. Splenectomy in myeloid leukemia usually proves speedily fatal; only one case is known in which the patient survived, and the leukemia did not seem to have been influenced in the least. Some clinicians have reported excellent results from splenectomy in pernicious anemia, but others have had only some improvement; the blood picture never returned quite to normal.

109. **The High Frequency Current in Arteriosclerosis.**—Bühler has been applying electricity in this form in 266 cases of arteriosclerosis. The blood-pressure was above 130 mm. in all but thirty-six, and in nearly every case the application of the high frequency current for about ten minutes caused a reduction of 5 or 10 mm. in the blood-pressure. In 120 cases with minute records, the average blood-pressure was 174 mm. at first and after seven sittings it averaged only 146 mm., a decline of 15 per cent. Reexamination a few months or years later showed that the reduction had been permanent in a number while in others the pressure had gradually risen again to its old figure. He explains the benefit as the result of a relaxing of the musculature of the vessels under the influence of the electricity on the nerves. The artery walls thus relaxed become more flexible and oppose less resistance to the pulse wave.

111. **The Dissolving Capacity of the Serum.**—Schade expatiates on the fundamental importance for medicine of the physicochemical properties of the blood serum. Beyond the

reach of the microscope but accessible to physicochemical research, the serum is found to possess a wonderful faculty for diffusion, dialysis, osmosis, ionization, influencing colloids, and forming intermediate colloids. The simplest and most accessible element of the body, it reveals what is going on in the cells, and the general practitioner should keep abreast with the progress of serology as it offers the key to manifold problems of clinical medicine, as Schade reviews in detail.

121. **Mercury Treatment of Progressive Paralysis.**—As long ago as 1887, Wagner von Jauregg published articles on the influencing of nervous and mental disease by an intercurrent febrile affection, even to the letting up of the symptoms of multiple sclerosis after an infectious sore throat. He has since accumulated considerable therapeutic experience in this line, which was the basis for his systematic treatment of general paresis with tuberculin; this he commenced in 1890. During that year he applied the tuberculin treatment in 69 cases of progressive paralysis and has been able to trace the history of 66 and also of 66 other patients under approximately the same conditions at the time and later except that no tuberculin had been given. Pilcz reported in 1910 a similar series of 60 patients. In a later series of 25 cases Wagner supplemented the tuberculin with mercury, as also Pilcz in a series of 86 cases. Meyer, Tamburini in Italy, Glouschkoff in Russia and others have also reported experiences in this line. The condition improves in nearly all the early cases to such an extent that the patients can return to business. Even in the advanced cases notable improvement may be realized and even complete remission in some cases. He has three patients restored to active business life, some with six or seven years to date of regained earning capacity. In the majority of cases, however, after a year or two of active business life the symptoms returned, but resumption then of the treatment was followed anew by a prolonged remission. The let-up in the symptoms begins during the treatment and continues to progress for several weeks thereafter. The regularity and constancy with which this occurs excludes any casual coincidence or a spontaneous remission; the extent to which the symptoms subside is also beyond anything observed in spontaneous remissions. He begins with 0.01 mgm. old tuberculin if there is no suspicion of tuberculosis; only a tenth of this dose is given when there is tuberculosis. The injections are made subcutaneously on alternate days or the third day increasing the dose to a final 1 mgm. This requires from eight to fifteen injections. He gives the mercury on the days between.

122. **The Dangers of Salvarsan.**—Luithlen's analysis of the mishaps after salvarsan shows, he says, that they are avoidable. All that is necessary is to determine the contraindications for it and keep the dosage reasonable. The dose of salvarsan should never be over 0.3 or 0.4 gm. All persons should be excluded from salvarsan treatment who are in a state of depressed vitality from any cause outside of the syphilis, or have any signs of cardiovascular injury or kidney trouble, chronic poisoning from alcohol, nicotin or lead, or infectious disease, including florid syphilis itself. Salvarsan, he reiterates, should never be given in the secondary stage of syphilis; it is not only injurious in this phase, but is much less effectual than mercury. Especially dangerous for salvarsan treatment are concomitant tuberculosis, severe gastro-intestinal disease and affections of the nervous system accompanied by destruction of pathologic tissue liable already to cause disturbance. Pregnancy is also a contra-indication on account of the changes in the vessels which seem to accompany pregnancy. Mercury should be given also unless the kidneys are pathologic; not only the albumin, but the diuresis should be heeded. He mentions that the latest compilation ascribes 274 fatalities to salvarsan, including 41 in nonsyphilitics; the injection had been subcutaneous in 9; in 28 into a muscle, and intravenous in the others. When the salvarsan has a toxic action, the symptoms which appear promptly are the work of the salvarsan as a whole; these then subside completely and only later, after a longer or shorter interval, other symptoms may develop which are the work of the arsenic as the salvarsan compound breaks up. He calls these the primary and the secondary toxic phases.

124. **Atropin in Stomach Disease.**—Pletnew expresses amazement that so little use is made of atropin in treating abnormal conditions in the stomach resulting from abnormal excitability and overaction of the vagi. He has made a special study for years of indications for and results of a course of atropin treatment in stomach affections, and states that it can be relied on when secretion or motor functioning or both are deranged or there are anatomic lesions in the stomach wall. He relates some typical cases in each of these three categories. Atropin checks secretion, reduces acidity, combats pylorospasm and hour-glass spasm, and relieves the pains, as the spastic conditions are the effect of excessive secretion of hydrochloric acid. The more acid the stomach content, the longer the pylorus waits before opening. Atropin, of course, has only symptomatic action, but in this field it renders most valuable service. Morphin also checks the pain but this is followed later by a stage of increased secretion. (See Spitzig on "Vagotony and Mucous Colitis" in The Journal, Jan. 31, 1914, p. 364.)

131. **Internal Hemorrhagic Pachymeningitis.**—Boeckmann gives a brief report of the autopsy findings in fifty-seven cases of internal hemorrhagic pachymeningitis with a view to determining to what extent trauma and hemorrhage are involved in the causation of the disease. He concludes that the importance of trauma has been very much exaggerated and that, in a healthy individual, trauma and aseptic hemorrhage cannot cause it. Its frequent appearance in the course of progressive paralysis would seem to indicate an inflammatory circulatory origin.

Wohlwill reports thirty-seven cases and states his opinion that the internal hemorrhagic pachymeningitis is due to a primary proliferation of the subendothelial tissue, probably from some preceding lesion of the endothelium. In the material from a general hospital, infectious diseases are the chief cause; alcoholism is not very important. The disease is frequent in children, especially in infants. Birth trauma is responsible in a great many of these cases.

134. **Effect on the Stomach of Removal of the Adrenals.**—Tinzi describes a series of experiments on rabbits and dogs and five autopsies on human subjects. In the animals after complete or partial abolition of adrenal functioning there were marked changes in the mucous membrane of the stomach consisting in circulatory disturbances, edema, hemorrhage and necrotic processes, the severest of which only exceptionally showed even slight tendency to heal. His reasons for assuming that the stomach lesions were caused by the adrenal disturbance are because they were less severe and recovered more readily when only one adrenal was removed; because they were not found in a rabbit which in spite of removal of the adrenals, showed no signs of decreased adrenal function; because the stomach lesions were not found when the operation consisted simply in removing the adrenal capsule, and because they were lacking when the rabbits after removal of the adrenals were given epinephrin or adrenals were transplanted from other rabbits. In five cases of stomach or duodenal ulcer in human beings, microscopic examination showed marked changes in the adrenals, thickening of the capsule, nodular hypertrophy, fatty degeneration, great congestion and multiple hemorrhages.

143 *Nourishment during Pregnancy and Weight of the Child. (Gewicht des Neugeborenen und die Ernährung der Mutter.) J. Bondi.

140. **Duodenal Ulcer.**—Schütz advocated an operation in only seventeen of his 137 cases of duodenal ulcer; 87 per cent. of the total patients were men. He is convinced that progress will be along the lines of internal treatment alone. He calls attention to the fact that the symptoms of duodenal ulcer—the duodenal syndrome—has long been known, but not correctly interpreted. It has been ascribed to a neurosis and all older physicians have had typical cases of this kind dragging along for years into an advanced age or sometimes subsiding completely, showing that a complete cure is not only possible but common. The diet with duodenal ulcer, he insists, should be different from the gastric ulcer diet. With the latter the diet should be restricted in quantity and quality to spare the stomach irritation, but this is less necessary with duodenal ulcer. Instead of fluid food which passes rapidly along, more compact food is needed with duodenal ulcer; this lengthens the period before the pains come on. Food should be given in small amounts at intervals not longer than three hours at most, not allowing the stomach to become empty, even during the night. A further important measure is to neutralize the excess of acid in cases with hyperacidity and hypersecretion—which is the rule with duodenal ulcer—by giving large doses of alkalies in combination with belladonna. He advises this regimen in eating to be kept up even during the intervals, supplemented by mental and physical rest and treatment of the common nervous disturbances. Another important measure is to ward off getting chilled or catching cold; this may require extreme precautions during the cold weather. A course at Carlsbad may often prove useful. Treatment on these principles has given him very favorable results in numbers of cases, not only in reducing the severity of the attacks but in modifying the predisposition. In many cases all disturbances subsided soon after beginning treatment, even when the periods of pain had lasted for months or had been recurring more and more frequently. In a few cases no benefit was derived from these measures until they were supplemented by application of cataplasms and a rest cure, with exclusive milk diet.

143. **Diet during Pregnancy and the Weight of the Child.**—Bondi does not agree with Peller, whose work on this subject was reviewed editorially in The Journal, Jan. 31, 1914, p. 382. The weight of the child is independent of the mother's diet during pregnancy, he affirms, but there is a direct connection between the chemical substance of the mother and of the fetus. Neumann has recently announced that the serum of the child contains far more mineral salts than the mother's serum; for this reason he advocates giving unusual amounts of the mineral salts during a pregnancy. Dibbelt witnessed the development of disturbances resembling osteomalacia in gravid rabbits kept on calcium-poor feed; the skeleton of the young seemed to be apparently normal. Bondi thinks that measures to increase the weight of the child are liable to do more harm than good, as increasing the difficulty of delivery; especially among the poor in whom the rachitic pelvis is so common, it is directly injurious to increase the weight of the fetus.

152 *Iodin Sterilization of Silk. (Metodo semplice e rapido di sterilizzazione della seta per sutura.) G. Liotta.

151. **Roentgen Treatment of Surgical Tuberculosis.**—Scaduto has only five cases to report, but the benefit from exposures to the Roentgen rays after operative treatment was so pronounced that he urges this combination as great progress. The tuberculous processes were in the knee or elbow, and he applied the rays from four directions and repeated the exposures every two weeks, for three, five or eight months. One boy of 6 had a tuberculous process in the sternum and it healed in less than six weeks after the focus had been curetted; only three exposures had been required in this case.

152. **Iodin Sterilization of Silk.**—Liotta winds a single length of the silk in a single layer on a glass slide. The slide is then immersed in tincture of iodin for from five to ten minutes for number 1 to 4 silk. He has been using this method of sterilization constantly for three years with perfectly satisfactory results, and commends it to those who do not have laboratory facilities at hand.

153 *When is Arthrodesis Required in Epidemic Poliomyelitis? H. A Laan.
154 *Action on Ovum of Superfluous Semen. (De beteekenis van het overtollige sperma voor de vrucht.) G. C. Nijhoff.

153. **Joint Fixation for Paralysis after Poliomyelitis.**—Laan remarks that too much is expected of tendon transplantation, and arthrodesis is liable to be done too soon, while Lorenz expects much from massage and forcible manual correction and warns against too ready resort to tendon transplantation or arthrodesis. What Lorenz has done for the Germans, Laan wishes to do for the Netherlanders, namely, to declare with all emphasis that joint fixation is seldom necessary and should never be done on children. He has seen complete

paralysis of the feet markedly benefited by the wearing of ordinary lace-shoes. If the resulting damage were better recognized, other methods would be employed in preference. Laan reiterates that the prevention of deformity is of prime importance; once developed, the deformity can be attacked by redressment or osteoclasis depending on the character and severity of the deformity and the age of the patient. Prevention of recurrence is of great moment and in many cases very difficult, especially among young patients; with grown persons it is much easier because growth has ceased and the tendency to recurrence is less. It is in these adult cases that the various methods of redressment, of tendon-transplantation or arthrodesis in its various methods can be employed. Laan is opposed to arthrodesis of the hip and knee; if it is necessary it must be a bony ankylosis. With drop-foot, in at least half the cases the joint works loose again. Even with perfect bony ankylosis, the patient often complains of unevenness of the soles and loss of endurance.

Laan is a strong advocate of silk ligament suspensions in cases not indicating arthrodesis. But for the shoulder, even Lorenz favors ankylosis of the shoulder on account of the anatomic construction and the nature of the paralysis. With paralysis of the deltoid muscle, the use of the joint is lost and all lifting movements of the upper arm have become impossible. The shoulder is moved principally by the deltoid muscle and the short muscles serve to form the scapula and the upper arm into a unit. This unit itself is moved by other muscles, attached to the scapula and humerus. When this fixation has become impossible, owing to paralysis, it must be reestablished. There are three methods to accomplish this: braces, arthrodesis and tendon transplantation. The brace is very unsatisfactory, and transplantation of tendons does little service here. Thus arthrodesis is the only resort, and this may give good results.

154. **Action on Ovum of Superfluous Semen.**—The text-books on physiology cite the countless numbers of spermatozoa at a single emission as an instance of the prodigality of nature when dealing with the perpetuation of the type, but Nijhoff has become convinced by the results of recent research that the superfluous spermatozoa may play an important part in the nourishment of the ovum. Spermatozoa have been seen to work their way into the mammalian ovum after the second, fourth, sixth and even eighth divisions. These spermatozoa entering the ovum after the impregnating spermatozoon may supply material for growth, but they can also be a vehicle for transmission of disease; the superfluous spermatozoa may come from another individual than the impregnating one. Possibly tuberculosis, syphilis and lead poisoning may be carried to the embryo in this way. It has been experimentally demonstrated that tubercle bacilli injected into the vagina may find their way inside the embryo. Nijhoff emphasizes that it is possible and probable that more harm may be done to the embryo by the superfluous spermatozoa than by the single one responsible for the fecundation of the ovum.

Nijhoff thinks that Constantin Paul's study of the effects of lead poisoning on the offspring is noteworthy from this point of view. Of the 142 pregnancies among women suffering from lead-poisoning, only forty-five resulted in a viable child and twenty of these died the first year; only ten survived past the third year. Almost similar figures have been published regarding the noxious influence of mercury and alcohol poisoning on the offspring.

160. **Treatment of Difficulty and Pain in Swallowing with Laryngeal Tuberculosis.**—Wetterstad discusses the various methods in vogue for this purpose, saying in conclusion that injection of alcohol around the nerve involved in the trouble seems to give the best results, while it is a very simple and apparently harmless procedure. By the technic advocated by Hoffmann, 85 per cent. alcohol is injected around the superior laryngeal nerve, introducing the needle from the side of the neck, along the lateral thyroid-hyoid ligament. Boncour makes the injection on the median line between the body of the hyoid bone and the angle of the thyroid cartilage. Wetterstad followed the first technic in six cases and the second in four, all the patients suffering severely from their advanced laryngeal tuberculosis. Complete relief from pain followed the injection, the relief persisting for fifteen or thirty days or longer. The injection seems to be easier and freer from pos ble complications when made in the median line.

162. **Diagnosis of Incipient Tuberculosis.**—Gade says that at the seaside sanatorium at Hagevik during the last five years there were only seventy-nine of the 1,150 children who had a tuberculous process in and probably restricted to the bronchial lymph-nodes. He reproduces sixteen of the 850 Roentgen pictures of lungs which he has taken, insisting on the fact that when the bronchial lymph-nodes have become enlarged, the tuberculosis has passed beyond its initial stage. It seems impossible really to detect the tuberculosis in its incipiency, but roentgenoscopy will reveal it in a much earlier stage than any other diagnostic measure.

164 Treatment of Sequels of Epidemic Poliomyelitis. H. C. L mann.
165 Calculation of Doses for Children (Beregning af Doser til Børn.) L. P. Sørensen and V. Sche

163. **Epidemic Poliomyelitis.**—Monrad describes the poi which are most useful to differentiate this disease from oth with which it may be confused, especially acute rheumati meningitis, appendicitis and polyneuritis. In some cases was erroneously diagnosed as dislocation of the humerus or hip-joint or fracture. Slight fever, vomiting and headache with more or less drowsiness are generally noted in the incipient stage. The mortality seems to be higher for older children and adults, and the fourth day seems to be the most critical one. The large number of abortive cases reported from the epidemics in Sweden suggests that there may have been a mistake in diagnosis. Monrad protests against too active treatment in the acute stage; he insists on absolute quiet, keeping the patient still in bed as long as there are signs of general infection or acute local disturbance, and during this period, which may last for three or six weeks, all treatment with electricity, massage or passive exercises should be carefully avoided, as the patient should be left in absolute repose. He denounces even baths, which are recommended here and there, "and are applied especially in North America." The position in bed must be comfortable and the limbs kept in good position, without pressure from the bed clothes, etc. It is important, he adds, to keep the bowels in good order, as the paralysis may involve the abdominal muscles. The only drugs he uses are mild sedatives to enable the child to rest and sleep. An important point in treatment of poliomyelitis is to tranquilize the family, reassuring them that the disease often ends in complete recovery and that, in 50 per cent. of the cases at least, the paralysis in time subsides to practical recovery.
